1. Introduction

Communities across the nation are experiencing changes in the natural hazards they face. Extreme weather events such as extreme heat, floods, and wildfires are occurring more often or during different times of the year. This makes it more difficult to plan for future incidents solely based on what has happened in the past. The evolving hazard landscape means emergency managers need to plan differently when assessing disaster risk and community resilience. To become more resilient, communities should examine the changing environment, understand how future hazards could unfold, and factor that information into their planning efforts.

1.1. Purpose

The Climate Adaptation Planning: Guidance for Emergency Managers (this guide) is intended to help state, local, tribal, and territorial (SLTT) emergency managers incorporate climate adaptation into emergency management planning efforts. It discusses climate science in the context of disaster preparedness and explains how emergency managers can help communities develop effective climate adaptation strategies. Communities may use different terminology around climate resilience and climate adaptation efforts, but for the context of this guide, the terminology will be subsequently referred to as “climate adaptation planning.”

The introductory section provides an overview of this guide and definitions of key terms. Section 2 provides an overview of climate science, regional impacts, and potential tools for climate modeling. Section 3 presents an overview of climate adaptation planning before section 4 follows up with the six step planning process based on Comprehensive Preparedness Guide (CPG) 101: Building and Maintaining Emergency Operations Plans. It also provides information and actions for each step. Section 2 can be read as reference material, whereas Sections 3 and 4 provides case studies and potential best practices emergency managers can take to plan for changes in climate. At the end of each section and step are key takeaways for emergency managers. The Appendices provide potential cascading impacts on response and recovery planning, more details on modeling tools, resources for financing climate resilience, information on trainings, glossary, and acronym list.

---

1.2. Key Terms and Considerations for Climate Adaptation Planning

- **Adaptation:** Adjustment in natural or human systems to a new or changing environment that exploits beneficial opportunities or moderates negative effects.\(^2\)

- **Climate mitigation (may also be called “mitigation” or “greenhouse gas [GHG] mitigation”):** Measures to reduce the amount and speed of future climate change by reducing emissions of heat-trapping gases or removing carbon dioxide from the atmosphere.\(^3\)

- **Hazard mitigation:** Any sustained action taken to reduce or eliminate the long-term risk to human life and property from hazards.\(^4\)

- **Nature-based solutions (NBS):** The sustainable planning, design, environmental management, and engineering practices that weave natural features and processes into the built environment to promote adaptation and resilience.\(^5\)

- **Resilience:** the ability to prepare for threats and hazards, adapt to changing conditions, and withstand and recover rapidly from adverse conditions and disruptions.\(^6\)

- **Risk:** Threats to life, health and safety, the environment, economic well-being, and other things of value. Risks are often evaluated in terms of how likely they are to occur (probability) and the damages that would result if they did happen (consequences).\(^7\)

Effective planning takes time and includes understanding potential future conditions, infrastructure, and impacts, along with proactive integration with other plans. Too often, planning occurs in silos which leads to conflicting community plans, especially in light of planning for the future with a dynamic climate. An example of this would be an economic development plan that identifies a waterfront district for expansion, which may conflict with a climate adaptation plan calling for greenspace in the area due to an expected rise in the sea level. Through efforts such as hazard mitigation and disaster recovery planning, emergency managers are in a key position to help bring different parts of the community together to harmonize long-term strategies that address the evolving climate as well as day-to-day planning challenges.

\(^6\) USGCRP. Fifth National Climate Assessment. (2023). [https://nca2023.globalchange.gov/chapter/1#box-1_1](https://nca2023.globalchange.gov/chapter/1#box-1_1).

**Hazard Mitigation versus Climate Mitigation for Emergency Managers**

Emergency managers often shorten the phrase “hazard mitigation” to “mitigation,” however, in the climate discipline, “mitigation” often refers to climate mitigation. Hazard mitigation is any sustainable action to reduce or eliminate long-term risk. Climate mitigation is the reduction of GHG emissions in the atmosphere to reduce the severity of human-caused climate changes.

Climate adaptation and hazard mitigation share a common goal of minimizing impacts from natural hazards that are expected to increase in frequency and intensity due to climate change. Climate adaptation is especially concerned with adjusting to future conditions and building resilience to withstand those changes. As the future climate is variable and may present new challenges, climate adaptation uses scenarios to help plan for uncertainty. Adaptation is also a process that continues over time, responding to new information or climate conditions. Successful climate adaptation solutions can vary depending on the scope of the action but often include changes in processes, behaviors, and infrastructure. Adaptations can shorten recovery by building communities that are more resilient for current and future hazards. Hazard mitigation and climate adaptation are essential because the effects of climate change are happening now and are expected to worsen.

As all-hazards planners, emergency managers already consider the impacts of an evolving climate through hazard mitigation planning. By adding climate adaptation planning, emergency managers can help promote climate resiliency across plans while supporting underserved populations and the whole community (see **Figure 1** for examples).

---

9 For more information on hazard mitigation planning requirements, see [https://www.fema.gov/hazard-mitigation](https://www.fema.gov/hazard-mitigation).
Key Takeaways for Emergency Managers: Introduction

- Extreme weather events are becoming more frequent and intense.
- It is important to understand key terms commonly used in climate adaptation planning, specifically the differences between hazard mitigation, climate mitigation, and climate adaptation.
- Climate adaptation planning seeks to assess climate-related hazards, develop courses of action to mitigate risk, and devise strategies for responding to climate-related disruptions.
- Emergency managers can help communities become more resilient by developing effective hazard mitigation and adaptation strategies to lessen the impacts of an evolving climate. They are in a key position to help bring different parts of the community together to harmonize long term strategies that address climate adaptation as well as day-to-day planning challenges in a comprehensive way.

2. Climate Science for Emergency Managers

Climate science investigates the structure and dynamics of Earth’s climate system. It seeks to understand global, regional, and local climate characteristics as well as the processes that influence change over time. Climate science is similar to the academic discipline of emergency management in that it draws on a number of scientific fields, including meteorology, oceanography, physics, chemistry, environmental science, informatics, and computer science. Climate scientists are increasingly working with engineers and social scientists across disciplines to understand and explain how changing climatic conditions will impact individuals, communities, economies, and infrastructure systems. This section describes the scientific underpinnings of the evolving climate and its potential impacts, provides potential data tools for analyzing changes in the climate, and introduces communication strategies needed to build climate-resilient communities.

2.1. Understanding Past and Potential Future Climate Conditions

Climate change is a broad term that can cover changes in multiple parts of the climate system, from temperature to precipitation to wind patterns.11 A region’s climate provides the background conditions that give rise to a location’s weather events. Thus, climate can be described as the “average weather” for an area; it refers to the average of the meteorological conditions and weather patterns that occur over long time periods.

Through geologic time, Earth’s climate has varied, reflecting the complex interactions and dependencies of the solar, oceanic, terrestrial, atmospheric, and living components that make up Earth’s systems. Earth experiences long cycles of warming and cooling that span tens of thousands to 100,000 years in length. The cycles are influenced by regular changes in Earth’s orbit that alter the intensity of the solar energy that the planet receives, absorbs, and reflects. Earth’s climate has also been transformed over a long timescale by changes in atmospheric chemistry and ocean circulation. It has also changed due to sudden events, such as massive volcanic eruptions into the stratosphere.

---

11 For more information on Climate Essentials for Emergency Managers, see https://www.fema.gov/node/climate-essentials-emergency-managers.
The rate of change in the climate during the 20th century and early 21st century stands out in the geological record as extremely rapid, especially relative to the last 10,000 years. Since the year 1900, global temperatures have risen by approximately 2°F, and climate scientists expect Earth’s temperature will continue to rise at an increasing rate throughout the 21st century. The key driver of this growing rate has been attributed to the emission of gases that trap heat in the atmosphere, commonly referred to as GHG.

**Greenhouse Gases**

GHG are gases that trap heat and solar radiation in Earth’s atmosphere rather than allowing it to escape into space. This process of heating the atmosphere is known as the greenhouse effect. GHG include carbon dioxide, methane, ozone, nitrous oxide, and industrial gases. Except for industrial gases, all are naturally occurring and are important for regulating Earth’s temperature. Human activities have increased the amounts of gases in the atmosphere, creating a disruption in the complex system of feedback loops in Earth’s warming atmosphere and climate.

The types and severity of change in the climate depend on how much GHG have built up in the Earth’s atmosphere. These gases have fluctuated over geologic time, yet human activities since the pre-industrial era, most notably fossil fuel burning, have exponentially increased the release of carbon dioxide emissions, resulting in a higher concentration of heat-trapping GHG and an increase in Earth’s average surface temperature (see Figure 2).

![Figure 2: Atmospheric Carbon Dioxide Amounts and Annual Emissions (1750 – 2021)](https://www.climate.gov/news-features/understanding-climate/climate-change-atmospheric-carbon-dioxide)

---

As it is not possible to determine exactly what future GHG emissions will be, climate scientists have created scenarios to better understand how human behavior will shape the future climate. Recently, these scenarios have been tied to societal narratives that describe potential challenges to climate mitigation and adaptation; these narratives are called Shared Socioeconomic Pathways (SSPs).

The Intergovernmental Panel on Climate Change (IPCC) uses SSPs for climate modeling scenarios that reflect change since the pre-industrial era. Each SSP is based on different assumptions of societal, demographic, and economic conditions that will either decrease, maintain, or increase future GHG emissions. For example, SSP2-4.5 describes a middle of the road scenario where significant action is taken to mitigate changes in the climate, yet emissions remain relatively high until midcentury. SSP3-7.0 is a scenario with many challenges in reducing emissions, while SSP5-8.5 describes a world with very high levels of fossil-fuel development throughout the rest of the century.

Table 1 and Figure 3 show the estimated impact of three scenarios on global temperature ranges.

Table 1: Shared Socioeconomic Pathways (SSP) Impact on Global Temperature by 2100

<table>
<thead>
<tr>
<th>SSP</th>
<th>Scenario</th>
<th>Global Mean Surface Temperature Increase in 2081-2100 Relative to 1850-1900 Time Period</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSP2-4.5</td>
<td>Intermediate: Fossil fuel carbon emissions peak mid-century, then decrease.</td>
<td>3.8° - 6.3°F (2.1 – 3.5° C)</td>
</tr>
<tr>
<td>SSP3-7.0</td>
<td>Higher: Assumes difficulty in reaching emissions reductions with slow mitigation.</td>
<td>5.0° - 8.3°F (2.8 – 4.6° C)</td>

17 The IPCC is an intergovernmental body of the United Nations responsible for advancing knowledge on climate change. It provides objective and comprehensive scientific information on climate change. It undertakes a periodic, systematic review of all relevant published literature and synthesizes the data and compiles key findings into "Assessment Reports."

18 The IPCC adopted SSPs as an update to Representative Concentration Pathways (RCPs) in its Sixth Assessment Report (2023; https://www.ipcc.ch/report/ar6/syr/). Many publicly available climate data still use RCPs, including some of the resources listed in this document. Fortunately, SSPs and RCPs share many similarities, with the second number in SSPs’ names matching several RCPs. For example, SSP5-8.5 is comparable to RCP8.5 and SSP2-4.5 to RCP4.5. Additional SSP scenarios have been developed, including scenarios with GHG emissions trends substantially lower than SSP2-4.5; however, we focus on the scenarios that most closely track with recent GHG emissions, ranging from intermediate to the highest emissions scenario. See USDA’s Climate Hubs for an explanation of SSPs and a comparison of RCPs and SSPs.

While the emission of GHG are currently the key driver of changes to the climate, other factors influence both short- and long-term atmospheric patterns. For example, changes in land cover can influence both weather and climate by altering the concentration of GHG and the exchange of energy between land and the atmosphere. Furthermore, reforestation can provide localized cooling, even as continued warming is expected for the planet as a whole and most regions on Earth.

Many factors will influence future GHG concentration including carbon capture and renewable energy technology advancements, governmental and organizational policy decisions, consumer behavior, and the pace of modernization in developing countries. Emergency managers are encouraged to remain up to date with current science and undertake climate-informed risk analysis, especially as it relates to climate impacts specific to a geographic region (see Regional Impacts).

### 2.2. Climate Impacts Globally and in the United States

The National Oceanic and Atmospheric Administration (NOAA) monitors how global climate data changes over time in its annual assessment. It also reports results through several Climate Change Indicators on its Global Climate Dashboard. On the next page are some of the NOAA Climate Change Indicators:

---

21 For additional U.S.-based indicators, see the USGCRP Indicators Platform: https://www.globalchange.gov/our-work/indicators?page=1
**Annual Greenhouse Gas Index:** Tracks the combined warming influence of the long-lived trace gases in the atmosphere.
- The amount of carbon dioxide in the atmosphere has risen by 25 percent since 1958 and by about 40 percent since the Industrial Revolution.\(^{22}\)

**Global Surface Temperature:** Tracks temperature measurements taken at locations around the globe, which are converted from absolute temperature readings to temperature anomalies.
- Global temperatures rose approximately 2°F (~1°C) from 1900 to 2022.\(^{23}\)

**Global Sea Level:** Tracks sea level estimates provided through tide gauges and satellite altimeters.
- Global sea level rise has accelerated from 1.7 mm per year throughout most of the 20th century to 3.2 mm per year since 1993.\(^{24}\)

In the United States (U.S.), emergency management response and recovery actions are being impacted due changes in weather- and climate-related hazards. Changing weather patterns will increase the severity, frequency, and impact of disasters. For example, the following list details hazards that are common in emergency management plans and provides examples of associated climate-related risk factors to consider:

- **Drought:** As temperatures climb, evaporation rates increase. In drought conditions, high evaporation rates will make droughts worse. Severe droughts can threaten drinking water supplies and supply chains, reduce industrial output, and disrupt agriculture.

- **Extreme Heat:** The annual number of very hot days is increasing. Extreme heat now regularly affects all areas of the country. Furthermore, the “urban heat island effect” can raise temperatures by up to 10°F within urban environments.\(^{25, 26}\) Of all weather-related hazards, extreme heat causes the highest number of deaths each year.\(^{27}\)

- **Coastal Flooding:** Rising sea levels are contributing to more frequent and intense coastal floods and storm surges, as well as recurring high tide flooding.

- **Inland Flooding:** In many regions, more frequent and intense rains are leading to more severe flooding, especially during the heaviest events. Heavy rain can also trigger flash flooding and

---

\(^{26}\) For more information on the urban heat island effect, see [https://www.heat.gov/pages/urban-heat-islands](https://www.heat.gov/pages/urban-heat-islands).

cause rivers to overflow. As extreme flood events become more common, the risk of dam failure is greater. Saturated soil also creates ideal conditions for landslides and mudslides.

- **Hurricanes**: Warming ocean waters fuel larger and stronger tropical storm systems and weather conditions and increase the likelihood of rapid intensification. The Caribbean, Gulf Coast, Southeast, and Mid-Atlantic are seeing more destructive hurricanes.

- **Wildfires**: Warmer temperatures are now more common, and intense droughts are creating the conditions for larger wildfires. Wet growing seasons, paired with dry periods, can lead to high fuel loads; warmer winter temperatures have allowed pests to decimate forest health, leading to massive amounts of dead wood on forest lands. All these factors create conditions for larger and more frequent wildfires and cascading smoke impacts.

This guide does not address all possible climate-related concerns and their potential impacts, as climate science remains an evolving discipline. For example, some climate research links extreme cold events to Arctic warming due to its influence on the jet stream; however, this finding is not yet well determined. Such cold air outbreaks significantly impacted people and infrastructure and should still be factored into planning.

### 2.3. Regional Impacts

Changing hazards will impact communities and regions differently. The hazards that regions and communities have been occasionally exposed to will become more frequent and severe. New areas will also be affected. Figure 4 outlines the top climate-related hazards for each region in the U.S. Note that this figure does not provide an exhaustive list of all climate-related hazards.

For a comprehensive summary of climate-related risk for each region, see the regional chapters in the *Fifth National Climate Assessment* and the 2022 State Climate Summaries. The next section provides a breakdown of potential climate-related impacts on communities by region.

---

2.3.1. POTENTIAL CLIMATE IMPACTS BY REGION

Northeast

- The Northeast is experiencing warming temperatures and a large increase in the amount of rainfall measured during heavy precipitation events.

---

32 Ibid. (Adapted figure).
Climate Adaptation Planning: Guidance for Emergency Managers

- Less distinct seasons, along with milder winters and earlier spring conditions, are already altering environments in ways that adversely impact tourism, farming, and forestry. For example, agriculture will likely face reduced yields as temperatures rise, potentially damaging livelihoods and the regional economy.
- More frequent heat waves in the Northeast are expected to increasingly threaten human health through more heat stress and air pollution.
- Sea level rise and more frequent heavy rains are expected to increase flooding and storm surges, threatening infrastructure.

**Southeast**

- Coastal communities in the Southeast are already experiencing warmer temperatures as well as impacts from sea level rise, such as more frequent and more severe flooding.
- Higher temperatures and greater demands for water will strain water resources.
- Incidences of extreme weather, increased temperatures, and flooding will combine with high rates of regional growth to have major impacts on human health, infrastructure, and agriculture.
- Sea level rise is expected to contribute to increased storm surges, resulting in more damaging hurricane and tropical storm events. Rising sea levels will increase the salinity of estuaries, coastal wetlands, tidal rivers, and swamps, damaging habitats and degrading aquifers.

**U.S Caribbean**

- Saltwater intrusion associated with sea level rise will reduce the quantity and quality of freshwater in coastal aquifers.
- Sea level rise, combined with stronger wave action and higher storm surges will worsen coastal flooding and increase coastal erosion.
- Projected increases in both average and extreme temperatures, resulting in higher levels of noncommunicable diseases, behavioral health challenges, and excess mortality.

**Midwest**

- Temperature increases in the Midwest have accelerated in recent decades, particularly increases in nighttime and winter temperatures.
- This region will likely experience warmer and wetter winters, springs with heavy precipitation, and hotter summers with longer dry periods. Extremes may pose challenges for agriculture.
- Risks to human health are expected to rise due to warming temperatures, reduced air quality, and increased allergens.
- Impacts to water quantity and quality are increasing the risks to ecosystem health, adequate food production, surface water and groundwater uses, and recreation.

---

**Great Plains**\(^{37,38}\)
- Warmer winters are altering crop growth cycles and will require new agriculture and management practices. Changes in water availability are likely to present challenges to agricultural irrigation and threaten key wetland habitats.
- Projected increases in temperature and drought frequency will further stress the High Plains Aquifer, the primary water supply of the Great Plains.

**Northwest**\(^{39}\)
- The Northwest is projected to face increased risks from extreme events, including flooding, landslides, drought, wildfire, and heat waves.
- The Northwest will likely be impacted by continued reductions in snowpack and lower summer stream flows in the Northwest, worsening the existing competition for water resources. Larger numbers of rain or snow events will also lead to additional flooding.
- Higher temperatures, changing stream flows, and an increase in pests, diseases, and wildfires will threaten forests, agriculture, and salmon populations.
- Sea level rise is projected to increase the erosion of most coastlines, escalating infrastructure and ecosystem risks.

**Southwest**\(^{40}\)
- Observations of rapidly warming temperatures and reduced snowpack have been observed in recent decades in the Southwest.
- Increasing temperatures and more frequent and severe droughts are expected to heighten competition for water for urban or residential use, agriculture, and energy production.
- Indigenous populations are expected to experience difficulties associated with access to freshwater, the sustaining of agricultural practices, and declines in cultural plant and animal populations.
- Drought, wildfire, invasive species, pests, and changes in species’ geographic ranges will increase threats to native forests and ecosystems.
- Experiencing unprecedented extremes related to changes in climate, resulting in potential droughts, larger and more frequent hailstorms, floods, and wildfires.
- Older residents in rural areas and Indigenous communities are especially vulnerable to increasingly severe and unpredictable climate impacts.

---

Alaska
- Extensive permafrost thaw is expected by the end of the 21st century, increasing the risk of infrastructure damage.
- Alaska is among the fastest warming regions on Earth, with temperatures warming twice as fast as the global average since the middle of the 20th century.
- Warming oceans will shift fisheries locations and impact productivity. Arctic sea ice is projected to continue to decline, with nearly ice-free periods possible by mid-century.
- Native Alaskans are expected to experience a declining availability of traditional foods and reduced access to sea ice hunting grounds.

Hawaii and Pacific Islands
- Dependable and safe water supplies for Pacific Island communities and ecosystems are threatened by rising temperatures, changing rainfall patterns, sea level rise, and increased risk of extreme drought and flooding.
- Warmer and more acidic oceans are stressing coral reefs and fish habitats.
- Sea level rise is expected to threaten biodiversity, ecosystems, and infrastructure of U.S. tropical islands.
- Changes in the climate are likely to affect the livelihoods of communities, tourism, and other important economic sectors on tropical islands.

2.4. Climate Impacts on People and the Economy

The frequency and complexity of disasters are increasing. According to NOAA, there were 28 climate-driven disasters with losses exceeding $1 billion within the U.S. in 2023. These events happened across all parts of the country and included droughts, floods, severe storms, tropical cyclones, wildfires, and winter storms that resulted in the deaths of 724 people. 2021 was the third-most costly year for weather and climate-related disasters in the U.S., with only 2005 (Hurricane Katrina) and 2017 (the California wildfires and hurricanes Harvey, Irma, and Maria) causing more economic impact. Since people live in high-risk areas, climate adaptation planning can play a key role in reducing human vulnerability, risk to the built environment, and economic impacts.

While the frequency and severity of disasters over the coming century will continue to increase, such changes are already being felt (see Figure 5). For example, in the 1980s, a billion-dollar disaster...
occurred approximately every four months on average.\textsuperscript{44, 45} Today, there is a billion-dollar disaster occurring every three weeks, on average. The physical, economic, and social impacts from these disasters are not distributed evenly. Disadvantaged populations are more likely to be exposed to the worst disaster impacts and possess fewer resources to cope with the effects.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{fig5.png}
\caption{Figure 5: Trends in Billion-Dollar Disasters Events (Inflation-Adjusted)}
\end{figure}

Rising global temperatures are the most observable impact of a changing climate, resulting in significant impacts on the frequency, severity, and geographical distribution of natural hazards. A warmer atmosphere means more intense storms. The warmer atmosphere can hold more water vapor, which results in increasing precipitation levels and higher risk of flooding. More heat in the atmosphere and warmer ocean surface temperatures can lead to increased wind speeds in tropical storms. Rising sea levels caused by melting glaciers and the thermal expansion of the ocean expose coastlines to tidal flooding and greater storm surge. All these impacts lead to increased damages.

For example, shifting precipitation patterns can lead to more prolonged periods of drought while greater evaporation rates dry out soils and reduce surface water. Reduced snowpack limits the replenishment of reservoirs, creating water shortages and straining agriculture and livestock production. These conditions can cascade to produce an environment conducive to the spread of wildfire, with dry soil and vegetation as ample fuel for fires. For more in-depth examples of climate-related hazards with direct and cascading impacts, see Appendix A.

Climate-related risks can compound with other hazards to create new threats or exacerbate existing ones. For example, long-term drought is accompanied by a greater risk of wildfire and wind erosion (e.g., the 1930s Dust Bowl). Coastal areas afflicted by riverine flooding as a result of intense

\textsuperscript{44} Ibid.

\textsuperscript{45} Billion-dollar event measurements are adjusted by the Consumer Price Index (CPI). The CPI is a measure of the average change overtime in the prices paid by urban consumers for a market basket of consumer goods and services. The CPI is a useful economic indicator, deflator of economic series, and a means to adjust dollar values.
rainstorms upstream may simultaneously experience a severe hurricane. This, in turn, could double the flooding impact and prolong the retreat of floodwater.

Extreme weather events, together with other natural and human-made health stressors, also influence human health in numerous ways. Some existing health threats will intensify, and new health threats may emerge. Not everyone is equally at risk due to social and economic inequities. Potential health effects of physical, biological, and ecological disruptions include increased respiratory and cardiovascular disease, injuries and premature deaths related to extreme weather events, changes in the prevalence and geographical distribution of food- and water-borne illnesses and other infectious diseases, and threats to mental health (see Figure 6).

![Figure 6: Impact of Climate Change on Human Health](image)

Climate threats may lead to other biological, technological, or economic threats. For example, extreme heat can reduce outdoor labor activities or damage infrastructure exposed to conditions beyond its design standards (e.g., melting roads, weakened bridges) or wildfire in one region can affect air quality and human health in other regions, depending on where winds transport smoke. Thus, different climate hazards can directly and indirectly affect a community or region’s economy, creating new risks for agricultural or natural resource-dependent industries (e.g., skiing, fishing). Individuals and businesses can also suffer from direct climate hazard impacts. This can include damaged workplaces; lost income; reduced tax base; disrupted supply chains; destroyed infrastructure, including power or internet; and inability to access a job site due to a damaged road.

---

Climate and Equity: Keeping Equity at the Center of Climate Adaptation Planning

Underserved communities are disproportionately impacted by climate-driven hazards. For example, Black, Indigenous, and People of Color (BIPOC) are more likely to reside in a highly vulnerable flood zone due to years of discriminatory housing policy.\(^4^8\) Lower income communities are more likely to work jobs with direct exposure to climate hazards (e.g., workers in extreme heat) and suffer greater harm from hazard-driven job disruptions or loss. Put simply, those with the fewest resources to cope with climate change are often the most vulnerable to its impacts.

Keeping equity at the center of climate adaptation planning is key to ensuring the entire community – not just a small subset – has access to the resources needed to adapt to climate change. Importantly, it also means ensuring underserved communities can meaningfully participate in decision-making, planning, and implementation of adaptation strategies. Action at the local level is vital in this regard, as building resilience occurs within a local, site-specific context. Emergency managers, elected and appointed officials, and other decision-makers are responsible for addressing climate impacts and the distribution of adaptation benefits by viewing the issue through an equity lens during every step of the planning process.

Climate impacts will affect many aspects of everyday life and may cause people and businesses to relocate. This relocation process will create both challenges and opportunities for communities, with some areas losing population and others needing to accommodate an influx of new residents.\(^4^9,^5^0\) Emergency managers, with their expertise in hazard mitigation and adaptation, can help to improve resilience for a community, and reduce involuntary relocation, through local climate adaptation planning.

Environmental Justice

Environmental justice (EJ) is the fair treatment and meaningful involvement of all people. The goal will be achieved when everyone enjoys 1) the same degree of protection from environmental and health hazards, and 2) equal access to the decision-making process to have a healthy environment in which to live, learn, and work.\(^5^1\)

---

2.5. Climate Informed Decision-Making for Emergency Managers

Emergency managers routinely influence and make decisions in highly uncertain situations. For instance, emergency managers may be asked to recommend protective actions for a hurricane with a 70 percent chance of landfall in their community in the next 72 hours, or for a chemical release with wind conditions that may shift in the next 30 to 90 minutes. In responding to these scenarios, emergency managers seek to minimize the risk while also arranging for the contingency that conditions may change. As the situation evolves and new information becomes available, emergency managers help leaders adjust risk management actions to cope with the evolving situation.

The decision-making approach used in planning, responding to, or recovering from disasters under uncertain conditions is similar to that applied to climate adaptation planning, albeit with a much longer timeline. Rather than operating over a period of hours or days, changes in the climate develop over years, decades, and even centuries. Adaptation plans are often implemented over similar timescales and usually reap rewards (e.g., risk reduction) over longer periods. Yet these plans also need to be revised and updated regularly as new information is gathered (such as updated projections of climate impacts). Climate adaptation planning should recognize that several potential outcomes can occur, especially related to GHG emissions, but also that non-environmental factors will influence the objectives and strategies of the plan.

Non-environmental factors that could impact jurisdictional climate adaptation planning include local economic growth and demographic change, urban development patterns, and transportation needs. Outside jurisdictional planning, individuals and businesses may contribute to adaptation. Examples include individuals installing solar panels or businesses upgrading buildings to increase energy efficiency in order to become more resilient to potential climate change impacts. By taking a broad approach to planning for an uncertain future, emergency managers can help to ensure that climate adaptation plans address a range of potential outcomes.

---

### Emergency Management and Policy Change

Some emergency management policy changes come AFTER large disasters, such as after Hurricane Katrina or Superstorm Sandy. Yet, local emergency managers may be in a unique position to address policy changes BEFORE disasters since they may be working with the elected or appointed officials as well as the whole community. A jurisdiction’s climate adaptation plan may be used to support future policy changes that consider climate adaptation and resilience.

---

2.6. Potential Tools for Climate Modeling

Many tools exist for potential climate modeling needs. Table 2 below provides information on tools’ applicability regarding social vulnerability, future conditions and some potential specific hazards. The Climate Resilience Toolkit also provides a website to start filtering for potential climate tools in relation to specific regions, hazards, or community needs. Using these tools, consistent with applicable laws, emergency managers can further engage with the public and various planning partners on potential decision-making for climate adaptation planning. For summaries on some of these tools, see Appendix B.

*Denotes availability of climate data using SSPs (current as of April 2024).

56 This list is not all-inclusive and represents the most commonly available and used tools for emergency management. Tools listed are often updated without notice. Capabilities identified are as of May 2023 by the FEMA Climate Team.
2.7. Communicating Changes in Climate

Communicating the degree of uncertainty associated with climate projections and information about ongoing hazard events is a key activity for emergency managers. They may think of public information activities primarily in the context of impending or ongoing disasters and emergencies. However, risk communications and public information can also include efforts to build awareness about how one or more hazards can affect a community. This includes communicating changes in climate for different contexts, such as ensuring that future flood risk is considered during the zoning and building permitting processes for new developments. More broadly, public outreach efforts can help community members understand that certain hazards may become more frequent and severe, and that all members of the community can adopt a solutions-based approach to these changing conditions.

Scientific Consensus on Climate Change

The U.S.’s foremost scientific agencies and organizations have recognized climate change as a human-caused problem that should be addressed. The USGCRP has published a series of scientific reports documenting the causes and impacts of global climate change. NOAA, NASA, and the EPA have all published reports and fact sheets stating that Earth is warming mainly due to the increase in human-produced heat-trapping gases.

Best Practices for Communicating Climate Change to Diverse Audiences

- Use terms that resonate with the target audience and find common ground. “Future risk” and “future conditions” may be good alternative terms to “climate change.”
- Leverage the power of story, such as through video. Data can be presented when woven within the context of an engaging story. Without a locally relevant story, focusing too much on the data may cause people to retreat from the conversation. Stories can make climate change more relatable.
- Focus on resiliency as well as climate change. Be sure to convey opportunities and a positive outlook. Get the audience excited about a climate resilient nation and let them know they have the power to be a changemaker.
- Collaborate with partners who the audience trusts and can carry the message for you.
- Avoid stereotypes. Members of the whole community, of all capacities, capabilities, and beliefs, are taking action to address changes in climates.

58 Climate stories NC, Click on individual stories at https://www.youtube.com/@climatestoriesnc6891/videos.
Climate can be a charged topic. Discussions around climate impacts can produce reactions ranging from denial to anxiety or depression. Therefore, it is important to ensure that information is science- and evidence-based research from trusted sources and discussions emphasize concrete actions to minimize climate impacts. Emergency managers can effectively communicate the benefits of climate adaptation by framing the impacts of climate change as “future risks” or “future impacts.” These terms highlight the frequency and severity of extreme weather events that may increase, such as hurricanes, heatwaves, wildfires, droughts, floods, and precipitation. The goal is to encourage individuals and businesses to actively help decrease climate-related risk exposure.

Some public meetings may allow for two-way dialogues and public concerns furthering discussions of potential adaptations that can lead to long-term community resilience and sustainability. For example, there could be a discussion on how land use and zoning processes might mitigate climate risks and provide additional social, economic and environmental benefits. Alternatively, local meetings might provide opportunities to talk about how infrastructure and building projects, such as using low-carbon materials, could be designed to address climate-related vulnerabilities.

**Key Takeaways for Emergency Managers: Climate Science**

- The key factor currently driving changes in climate are the emission of gases that trap heat in the atmosphere, commonly referred to as greenhouse gases (GHG). Since future GHG emissions remain unclear, climate scientists created multiple potential futures; referred to as Shared Socioeconomic Pathways (SSPs).
- To be prepared for an uncertain future, emergency management planners should consider a broad variety of scenarios and potential cascading disaster impacts on people and the economy in their geographic region.
- It is important to keep equity at the center of climate adaptation planning efforts as underserved communities are disproportionately impacted by climate change and climate-driven hazards.
- Emergency managers can use a combination of climate modeling and social vulnerability tools to support planning and decision-making in uncertain future climate conditions.
- To communicate climate change threats to the public, emergency managers can focus on terms such as “future risk” or “future conditions” to show how climate impacts may affect individuals and the whole community.

60 NASA, Vital Signs of the Planet: What’s the Difference Between Climate Change and Global Warming? (2024).
3. **Climate Adaptation Planning: An Overview**

Climate adaptation planning requires planners to think in terms of decades rather than months or years. While there is uncertainty regarding the severity of climate impacts, there is little doubt that emergency managers can plan for more frequent and more severe climate-driven incidents. Emergency managers will have a leading role in preparing communities for new risks that will be driven by the evolving climate.

3.1. **Principles of Climate Adaptation Planning**

Climate adaptation planning starts with understanding the types of climate-related hazards and risks a community will face. This begins with reviewing weather-related disasters that have occurred in the past and then projecting how future climatic conditions may change traditional hazards and create new climate-related risks. Consideration of future climate conditions can be integrated into existing risk analysis and planning activities, such as the Threat and Hazard Identification and Risk Assessment (THIRA), hazard mitigation plans, and the development of mitigation and recovery strategies, plans, and exercise materials. Once a community has this information, they can identify how they are likely to be affected by all-hazards. Specifically, they can estimate which geographic areas, population groups, community services, and critical infrastructure elements are vulnerable.

In collaboration with a diverse set of community members, planners can then identify strategies and actions for adapting to these new risks. An inclusive, community-wide approach is essential to ensure that the planning process and the goals, objectives, and strategies are equitable. This means identifying and prioritizing the needs of underserved groups and ensuring equal access to the benefits of adaptation. A climate planning process that is both equity-focused and informed by science will help produce a quality climate adaptation plan. Ultimately, climate adaptation principles should be incorporated into all community planning processes.

---

**Climate and Equity: Portrayal of Underserved Communities**

The [United Nations](http://www.un.org/en/climatechange/communicating-climate-change/) states “Poorer countries and underserved communities, including [Indigenous peoples](http://www.un.org/en/climatechange/communicating-climate-change/) who have protected the environment for generations, are often portrayed solely as victims of climate change, rather than positive agents of change. The same is often the case for women and girls. Make sure to highlight the voices, expertise, innovations, positive action, and solutions by people from all walks of life and communities from all parts of the world.”

While climate adaptation planning is a heavily technical process due to its reliance on risk data and climate models, it will be most successful when it is people-centered, collaborative, and equitable. This includes building partnerships across the whole community, collectively proposing creative strategies, and sharing decision-making responsibilities to reduce risk from climate change while preserving what the community values most.

---

3.1.1. **CLIMATE ADAPTATION PLANNING PRINCIPLES**

Preparing for climate-related disruptions is a key part of creating climate-resilient communities; however, climate adaptation planning goes beyond preparedness and disaster response. Adaptation planning involves implementing policies, management strategies, and long-term investments as part of a community-wide approach to reduce climate-related risk. The following four principles are fundamental to climate adaptation planning:

**Focus on the Future:** Even though recent disasters have raised awareness of the impacts of extreme weather, future climate conditions are likely to be different than what communities have experienced in the past. Planning for climate resilience involves planning periods of decades or longer. Planners should factor in how changing climate conditions might interact with other aspects of a community. Some non-environmental factors include development patterns, population demographics, and emerging technologies (e.g., new methods of transportation). This inherent uncertainty is an important aspect of climate adaptation planning.

**Link to Community Planning Processes:** Most communities have well-established planning processes that provide the infrastructure, services, land use, economic development, and public health foundations for a community to thrive and prosper over time. Effective climate planning can be integrated into these planning efforts so that strategies are put into place to adapt existing services, infrastructure, and capabilities to withstand future climate-related challenges.

**Leverage Partnerships and Relationships:** Just as community planning processes strive to be transparent and provide opportunities for public and stakeholder engagement, it is particularly important for outreach and engagement to be part of climate adaptation planning. Adapting to future climate stressors (e.g., long-term trends that increase vulnerability) is a relatively new concept, and it is important to ensure community members and key stakeholders are aware of the threats posed by a changing climate and the ways in which these impacts could affect different parts of the community.

**Use a Multidisciplinary Approach:** Climate adaptation planning involves the integration of social, economic, and environmental considerations to promote innovative solutions that are socially acceptable, viable, equitable, sustainable, and increase resiliency. Climate adaptation planning is most effective when it incorporates multi-disciplinary strategies based in natural science-, social science-, and engineering to increase the communities’ resilience to climate-related disruptions.

**Examples include:**
Natural sciences help in understanding the risks caused by climate change, particularly those important to habitat and biodiversity. This information can be used to mitigate impacts on wildlife, such as fisheries. Nature-based solutions (NBS) can also increase resilience through the integration of natural features into the built environment, helping to reduce flood risk, lower urban heat, and more. Examples include wetland restoration, permeable pavement, green roofs, and living shorelines.62

Social sciences provide important context for understanding and responding to the public health, economic, and equity impacts of climate change. Social sciences can provide information about the impacts that climate change will have on people and encourage sustainable practices that best fit the needs and culture of the community. An example is using local public health data to inform improvement strategies that incorporate future climate changes.

Engineering offers effective and innovative strategies for adapting to the impacts of climate change and the possibility of novel approaches in the future. For example, there are opportunities to integrate the engineering of stormwater infrastructure (e.g., flood levees, drainage systems, rainwater retention measures) and natural systems into a mutually reinforcing and cost-effective approach for environmental management.63 These approaches can also benefit climate mitigation, such as by reducing building energy use.

Many communities also undertake pre-disaster recovery planning64 that establishes strategies to lessen disruptions following a disaster. These recovery strategies can be a useful foundation for climate resilience in traditional planning. Aligning strategies and leveraging funding opportunities can also contribute to a cohesive community climate adaptation strategy. These strategies can include using traditional ecological knowledge.

---

62 For more information on NBS, see https://www.fema.gov/emergency-managers/risk-management/nature-based-solutions.

3.2. Climate Funding and Adaptation Solutions for Emergency Managers

An important question to ask is, are established planning processes flexible enough to consider adaptation and associated equity concerns, or do the processes need to change? Leveraging funding opportunities through emergency management may provide potential solutions.

Before Disasters: Emergency managers work with—and invest funds in—communities to build a nation able to withstand the climate hazards of today and those we can anticipate.

- FEMA programs like the Building Resilient Infrastructure and Communities (BRIC) and the Flood Mitigation Assistance (FMA) grant programs provide resources so communities are better prepared before disasters or extreme weather events strike.66
- The National Exercise Program provides support to federal and SLTT government partners to assess and enhance response and recovery capacities.67
- FEMA grants allow for investment in the infrastructure, including NBS and adoption of hazard-resistant building codes, and response and recovery capabilities.68
- FEMA manages the National Flood Insurance Program which enables property owners to transfer their financial risk through the purchase of flood insurance.69

---

65 Figure adapted from: Status of Tribes and Climate Change Report, Institute for Tribal Environmental Professionals, Northern Arizona University, Flagstaff, AZ. (2021). [http://nau.edu/stacc2021](http://nau.edu/stacc2021).

67 For more information on the National Exercise Program, see [https://www.fema.gov/emergency-managers/national-preparedness/exercises/about](https://www.fema.gov/emergency-managers/national-preparedness/exercises/about).

68 For more information on FEMA grants and Building Codes, see [https://www.fema.gov/grants](https://www.fema.gov/grants) and see [https://www.fema.gov/emergency-managers/risk-management/building-science/building-codes-strategy](https://www.fema.gov/emergency-managers/risk-management/building-science/building-codes-strategy).

69 For more information on the National Flood Insurance Program, see [https://www.fema.gov/flood-insurance](https://www.fema.gov/flood-insurance).
After Disasters: Emergency managers provide information and funding to help SLTT officials strategically invest in building back to increase climate resilience.

- FEMA’s Hazard Mitigation Grant Program (HMGP), including 406 Public Assistance Grants and Post-Fire assistance, goes beyond just rebuilding; these grants fund efforts for building back stronger and more resilient to future threats.\(^{70}\)
- The Inflation Reduction Act (IRA)\(^{71}\) enables FEMA to fund costs associated with low-carbon materials to help cut carbon pollution (GHG) to support climate resilience in communities.\(^{72}\)

Communities must have an approved hazard mitigation plan to apply for certain non-emergency FEMA funding. More information can be found [here].\(^{73}\)

### Resources Available to Support Communities

**FEMA Resources for Climate Resilience** provides a comprehensive explanation of FEMA programs planning for climate change.\(^{74}\) Appendix C highlights other potential federal, state, local, private, and philanthropic funding sources.

Climate adaptation strategies often have short- and long-term benefits beyond enhancing community resilience. For example, using NBS to expand the flood water-carrying capacity of lands adjacent to a river could provide recreational, aesthetic, biodiversity, and quality of life benefits to a community (see Figure 8). Benefits for other types of strategies might be linked to economic development, public health, air and water quality, and improved housing. In some situations, climate adaptation strategies could also contribute to reductions in GHG emissions.

Incorporating climate resilience principles throughout community planning can help reduce the likelihood of engaging in maladaptation. Examples of maladaptation include building seawalls that then shift vulnerability to people elsewhere or eliminating floodplains, which in turn reduces the nutrients in soils previously provided by flood water.\(^{75}\) Officials who are often tasked with budgeting for community services and capital investments should incorporate climate-related risk and sustainability considerations into their decision-making processes.

---

\(^{71}\) For more information on the IRA, see [https://www.whitehouse.gov/cleanenergy/inflation-reduction-act-guidebook/](https://www.whitehouse.gov/cleanenergy/inflation-reduction-act-guidebook/).

\(^{72}\) For more information on low-carbon goals, see [https://www.fema.gov/grants/policy-guidance/low-carbon-goals](https://www.fema.gov/grants/policy-guidance/low-carbon-goals).

\(^{73}\) For more information on mitigation planning grant requirements, see [https://www.fema.gov/emergency-managers/risk-management/hazard-mitigation-planning/requirements](https://www.fema.gov/emergency-managers/risk-management/hazard-mitigation-planning/requirements).

NBS projects can be larger in size in rural or less developed areas. These solutions reduce risk for communities by working at the source in coastal, mountain and rural lands nearby.

In more developed areas, small NBS and hybrid projects can add up over time. Many different types of NBS can work across a community to reduce risk at a larger scale.

Figure 8: Examples of Nature-Based Solutions Across Landscapes

Types of Adaptation

- **Low-Regrets**: Low-regrets actions are cost-effective now and under a range of future climate scenarios and do not involve hard trade-offs with other policy objectives. These actions are relatively low cost and provide relatively large benefits under predicted future climates. They contribute to adaptation while also having other social, economic, and environmental policy benefits, including benefits related to mitigation. Examples include efforts to improve water and energy efficiency; preserving landscapes in support of biodiversity; and land use planning to minimize flood hazard exposure.

- **Incremental**: This adaptation pathway involves discrete actions that minimize present-day climate impacts. Typically, these actions follow a climate-related disruption and target solutions to a specific event or vulnerability. Examples include increasing stormwater and wastewater capacity; building flood protection; designing buildings to meet future climate demands; and increasing water reservoirs.

- **Transformational**: Transformative adaptation involves large-scale changes that contribute to long-term societal resilience and sustainability. This can emerge from both individual and collective action and takes a long-term perspective while recognizing diverse constituent interests. Transformational adaptation may involve institutional reform, structural changes, and coordination across multiple levels of governance. Examples include funding the relocation of underserved communities; changing land use patterns to restrict use in high-risk areas (e.g., wildland fires, flood-prone areas); and prioritizing protecting ecosystems.

- **Maladaptation**: Maladaptive responses to climate-driven events are those that end up increasing or shifting vulnerability and reducing community resilience. Such actions may address short-term risks, but in the long run increase disaster exposure. Examples include planting trees in wildfire-prone areas and neglecting underserved communities.

Climate adaptation strategies are also often more effective when implemented across many different communities without pushing the impacts into other jurisdictions. Regional coordination can lead to:

- Consensus on which future climate scenarios should be used in vulnerability analyses;
- Identifying the types of mitigation and adaptation strategies that would be most cost-effective;
- Sharing of data, tools, and other resources for climate as well as response and recovery operations; and
- Identifying the types of mitigation and adaptation strategies that require collaboration across the region’s communities to reach their full benefits.
3.3. Connecting Hazard Mitigation and Climate Adaptation Planning

Climate adaptation planning, although it covers all mission areas, can take advantage of relevant existing mitigation plans and activities. All 50 states, the District of Columbia, and U.S. territories have FEMA-approved hazard mitigation plans, as do more than 224 Tribal Nations and 24,700 local governments. These mitigation plans and the information developed for them can provide a useful component of, and a launching point for climate adaptation planning. Furthermore, emergency managers’ experience in hazard mitigation planning provides an opportunity to assume a leadership or coordinator role in climate adaptation planning. When emergency managers do not have the technical expertise in climate adaptation, they can use their role to ensure the core planning team includes climate experts such as local staff with climate knowledge, academic researchers, state climatologists, or other agency representatives (e.g., NOAA, National Weather Service).

The mitigation planning process shares some fundamental similarities with the process outlined in this document, such as organizing the planning process, assessing risks and capabilities, developing the plan, and then adopting and implementing it. However, the planning process differs slightly for SLTT governments, with different laws and regulations guiding the development of each type of plan and an action strategy or roadmap.

FEMA’s Mitigation Planning Program

FEMA’s Mitigation Planning Program is a useful resource to aid in the development of state or community level climate adaptation plans. The program can help establish a foundation or be used as a source of information to integrate into climate adaptation plans. Dedicated hazard mitigation planning policy guides for state, tribal, and local governments, technical assistance and training resources are available at https://www.fema.gov/hazard-mitigation.

Case Study: Colorado Combining Climate and Hazard Mitigation Planning

In 2019, the State of Colorado established the Future Avoided Cost Explorer Tool which helps local planners incorporate climate into their jurisdiction’s hazard mitigation plans by exploring the economic impacts from flood, drought, and wildfire in 2050. Larimer County used the tool to forecast that under a medium growth and moderate climate change scenario, the County will see $59 million in annual damage from these three hazards by 2050 (see Figure 9), which is 2.6 times the current level. Post 2020 wildfires, Larimer County used HMGP grant funding to establish a Climate Smart Future Ready Plan which identifies actions the County can take for mitigation, adaption, and resilience to hazards under climate change. The Plan includes

---

77 These FEMA approved hazard mitigation plan numbers are accurate as of the publication of this guide.
78 For more information on the Future Avoided Cost Explorer Tool, see https://cwcb.colorado.gov/FACE.
79 For more information on the Climate Smart Ready Plan, see https://www.larimer.gov/climate-and-sustainability/climate-smart-future-ready.
understanding how the community perceives current and future climate change impacts and what they see as challenges and appropriate responses for the unique North Front Range context. Additionally, the Climate Smart and Future Ready Plan integrates with Larimer County's Multi-Jurisdictional Hazard Mitigation Plan, as it is a Mitigation Action Item that was identified through the local hazard mitigation planning process.

Figure 9: Larimer County’s use of Colorado’s Future Avoided Cost Explorer Tool

Source: https://cwcb.colorado.gov/FACE.

Updated hazard mitigation planning policies reinforce resilience as a whole community effort. State and local hazard mitigation plans must now address current and future risks, including those from climate change, land use, and population change. These risks, which are strengthened or worsened by climate change, must be analyzed in how they impact community sectors (e.g., housing, economy, infrastructure, natural systems and resources) and socially vulnerable populations. The policies support mitigation planning's integration with other complementary community actions, such as climate adaptation, resilience, and sustainability planning initiatives.
In hazard mitigation plans, emergency managers and planning teams should directly address climate risks for each hazard and could develop adaptation solutions, including potential funding sources to ensure these actions are attainable. Hazard mitigation plans should also incorporate and reference any goals and actions in relevant state, tribal, or local climate plans. These efforts build state, tribal, and local capabilities and help jurisdictions plan for long-term risk reduction, climate change, and more equitable outcomes.80

Hazard mitigation planning can be used to strategically advance climate adaptation efforts and can be a useful mechanism for securing funds for projects that achieve both hazard mitigation and climate adaptation goals. The Disaster Mitigation Act of 2000 created the framework for SLTT governments to engage in hazard mitigation planning to receive certain types of non-emergency disaster assistance. Governments with approved and adopted hazard mitigation plans may be eligible for a number of FEMA grants,81 including:

- Hazard Mitigation Grant Program (HMGP)
- Categories C-G of the Public Assistance Grant Program (PA)
- Building Resilient Infrastructure and Communities (BRIC)
- Rehabilitation of High Hazard Potential Dam Grant Program (HHPD)

For more information on these programs, along with other funding opportunities, see Appendix C.

Key Takeaways for Emergency Managers: Climate Adaptation Planning

- Consider integrating projected climate conditions into existing risk analysis and planning activities, such as the THIRA, hazard mitigation plans, and the development of mitigation and recovery strategies, plans, and exercise materials.
- Climate adaptation planning is most effective when it incorporates natural science-, social science-, and engineering-based strategies such as NBS.
- Leverage diverse funding opportunities (emergency management grants, other government funds, or public and private sources) and work across different communities and jurisdictions to be most effective.
- Connect hazard mitigation planning efforts, partners, resources, and funding opportunities to climate adaptation goals and strategies whenever possible.

80 For more information on Hazard Mitigation Planning Policy updates, see https://www.fema.gov/emergency-managers/risk-management/hazard-mitigation-planning.
4. **Climate Adaptation Planning: Six-Step Planning Process**

This section provides a step-by-step process for integrating climate adaptation principles into emergency management planning. While this section presents the planning process from the perspective of developing a stand-alone plan, the process and its outputs can also be used to incorporate adaptation concerns into other community plans, such as:

- Hazard mitigation plans (comprehensive or specialized);
- Emergency operations plans (EOPs) and appendices;
- Recovery plans and strategies;
- Local comprehensive and land use plans;
- Economic development plans;
- Transportation and capital improvement plans;
- Sustainability and climate action plans;
- Community health assessments and community health improvement plans; and
- Water and land management plans.

This section builds upon the scientific and analytical approaches addressed in Section 2. It also proposes guidance on the integration of climate-related risks and adaptation principles into a community’s broader planning processes and institutional structure.

**U.S. Climate Resilience Toolkit**

The [U.S. Climate Resilience Toolkit](http://toolkit.climate.gov) has a user-friendly Practitioner’s Guide for Implementing Steps to Resilience. While there are some differences between the Toolkit’s Steps to Resilience (see Figure 10 at right) and this FEMA guide, which is specific for emergency managers, the fundamental approach and actions are similar. This FEMA guide aligns the key climate adaptation planning actions included in the U.S. Climate Resilience Toolkit to the six-step planning process outlined in FEMA’s CPG 101 (see Figure 11 on next page).

---

83 For more information on the Practitioner’s Guide for Implementing Steps to Resilience, see [https://toolkit.climate.gov/content/practitioners-guidance-implementing-steps-resilience](https://toolkit.climate.gov/content/practitioners-guidance-implementing-steps-resilience).
Climate Adaptation Planning has a higher degree of uncertainty and should consider multiple future climate scenarios. Traditional emergency planning often relies largely on historical data. However, climate change necessitates a shift to focusing primarily on future climate scenarios. As it is not possible to know what future emissions levels and climate mitigation policies will be, adaptation planning should consider multiple climate scenarios (e.g., intermediate emissions, high emissions) and recognize that some impacts may be difficult to predict.

Climate adaptation planning is an iterative process. It cannot be completed once and then set aside for 15 years. Knowledge of climate science and climate-related vulnerabilities is constantly evolving. Likewise, community factors such as demographics and key institutions change over time. Therefore, climate adaptation plans need to be monitored and adjusted regularly to ensure adaptation strategies are effective.

Climate adaptation planning should be a key part of all community planning. While stand-alone climate adaptation plans are important, climate adaptation planning and strategies should be woven into all emergency and community planning efforts. For example, a decentralized energy system using solar power can be taken down before big storms and then reinstalled after to reduce potential loss of power.

The following sections walk through each step of the planning process, highlighting the key actions for climate adaptation planning.
4.1. Step 1: Form a Collaborative Planning Team

The first step of the planning process is to form a collaborative planning team. This begins with identifying the core planning team members who are responsible for the bulk of the analysis and planning activities. Efforts are then expanded to identify the broader collaborative planning team members and processes to ensure whole community engagement.

Questions to Consider When Forming the Collaborative Planning Team

- How does the jurisdiction define a climate-resilient community?
- What does success look like for this effort, and what are possible barriers or challenges to achieving this success? What is the target timeframe for developing the plan?
- How can the planning team take advantage of existing planning and preparedness activities (such as hazard mitigation planning and community preparedness efforts) to inform the planning effort?
- What types of education, outreach, and advisory structures should be established to encourage awareness and participation in the planning effort?
- How will the products of this effort be used to inform community or governmental decision-making?

Climate adaptation planning touches on all aspects of community life and requires the engagement of a broad range of stakeholders. Emergency managers have expertise in areas that are essential to adaptation planning, such as hazard identification and risk management. They also have knowledge of community resources and local characteristics. Depending on the jurisdiction, the emergency manager may serve in a coordinating role for the planning effort.

Climate and Equity: Environmental Justice (EJ) Based Decision Making

Emergency managers can make more equitable EJ-based decisions by targeting resources and grants to the underserved and integrating EJ into communications and directives. Emergency managers can also collaborate with historically underserved communities to ensure their perspectives and knowledge are included in climate adaptation planning and decision-making.

Climate adaptation planning is most successful when people with skills and expertise in many areas are part of the effort. The specific expertise needed for the planning team will depend on the geographic scope of the planning effort, the characteristics of the jurisdiction, and the scope of
activities. Examples of expertise that may be needed on the planning team include climate science, engineering (e.g., structures, transportation, water resources), community planning, public and behavioral health professionals, public engagement strategies, social impact assessment, economic development, and finance. The core planning team may also establish advisory committees (e.g., technical, public) to assist on issues such as the preservation of historic resources and to ensure the interests of underserved and marginalized communities are heard with meaningful engagement.

**Case Study: City of Miami, Florida Climate Resilience Committee Members**

The [Miami Climate Resilience Committee](#) includes a list of characteristics that should be represented by the Committee Members:

- All members shall be city residents, work in the city, own a business in the city, or own real property in the city.
- One (1) member with expertise in infrastructure, civil engineering, or architecture.
- One (1) member with expertise in community and real estate development.
- One (1) member with expertise in climatology, geophysics, coastal management, oceanography, or coastal ocean science.
- One (1) member with expertise in emergency management.
- One (1) member with expertise in advocating for vulnerable low-income communities.
- Two (2) members who are eighteen to twenty-five (18 – 25) years of age and possess a strong interest or education in climate resilience including but not limited to impacts on infrastructure, water supply and quality, ecosystem health, housing, socioeconomics, or advocacy for vulnerable low-income communities.

During this initial step of the planning process, the planning team may also find it helpful to discuss and document some preliminary planning goals and considerations to help guide the effort.

**Key Takeaways for Emergency Managers: Step 1**

- Lead or participate in scoping efforts to identify preliminary goals and considerations.
- Identify key participants in hazard mitigation and community preparedness planning who could participate in climate adaptation planning.
- Describe funding opportunities for mitigation, community preparedness, and adaptation strategies, programs, and projects.
- Advocate for broad representation on the planning team to include individuals with disabilities and others with access and functional needs as well as those that have been historically underserved.
4.2. **Step 2: Understand the Situation**

The second step of the planning process focuses on developing a solid understanding of the community and its needs, resources, and risks. This information will inform the identification of goals and objectives in Step 3 and the identification of adaptation strategies in Step 4. After forming the collaborative planning team, this second step is important in identifying a common language to use prior to prioritizing goals and objectives. While this step focuses on identifying the community’s climate-related risks, it is also important to document key community characteristics and needs.

**Questions to Consider When Examining Risk and Vulnerability**

- What are the demographics of the community?
- What populations have been historically underserved and what challenges do they face?
- What infrastructure, facilities, assets, community services, and cultural or historical features are important to the community and need to be protected?
- What other voices are needed in this planning process?
- What areas will be most affected by future climate conditions as seen in climate modeling?

Regarding the community’s climate-related risks, there are two key actions: 1) collecting and evaluating data and information on historical and projected climate conditions, along with the resulting threats and hazards, and 2) assessing current and future levels of risk to the community’s people, assets, infrastructure, and services.

**Evaluate Historical and Future Climate Conditions**

Identifying and understanding past extreme weather-related events is an important starting point. Many of these hazards are likely already identified in the community’s hazard mitigation plan. This historical data provides a useful backdrop for evaluating how climate change will amplify current hazards, as well as potentially create new ones; however, it is not sufficient to rely on historical data alone. Planners should be familiar with widely used climate projections and understand how they may impact local conditions.

The selection of which scenario(s) to use in climate adaptation planning is a critical decision. Jurisdictions may choose to select:

1) A single scenario—for example, the worst-case scenario (not recommended but jurisdictions may be constrained by time or resources).
2) Multiple scenarios—such as a low, medium, and high scenario—to establish a range of possible outcomes. For example, Louisiana’s 2017 coastal master plan used three climate scenarios to project future land changes (land lost in red or gained in green) over the next 50 years (see Figure 12). Using multiple scenarios best captures the range of future climate uncertainties.

![Figure 12: Example of Climate Scenarios Used in Louisiana's Coastal Master Plan](https://coastal.la.gov/wp-content/uploads/2017/04/2017-Coastal-Master-Plan_Web-Book_CFinal-with-Effective-Date-06092017.pdf)

The plan should also communicate the uncertainties associated with the key variables being used to create objectives and strategies. For example, coastal communities that need to plan for sea level rise should consider and communicate the difficulty of modeling rapid ice cap melting, which makes projecting the upper bounds of sea level rise difficult.

Once the planning team has selected a climate scenario(s), they can use climate modeling resources, such as those covered in Section 2.6, to evaluate predicted future impacts. Comparing these impacts to historical data (e.g., historical heat waves, flood levels) will enable the planning team to estimate how the type and severity of climate impacts are expected to change.

**Assess Vulnerability and Risk to Community Assets and Services**

Once the planning team has predicted the types and severity of future hazards, they can conduct a risk assessment. The risk assessment examines how vulnerable the community or a particular facility, asset, service, or population is to the impacts of predicted climate hazards. Risk

---

assessments are the basis for determining which adaptation strategies will provide the greatest risk avoidance and reduction.

In some cases, risk can be determined with a relatively high level of accuracy. For example, with projected flooding impacts on infrastructure, a simple engineering analysis can determine if a highway, bridge, building, electrical grid component, or element of the telecommunications infrastructure will be compromised and possibly damaged. The planning team can then use this information to estimate the level of damage that might occur and thus the costs of replacing or fixing the damaged components. However, for other types of vulnerabilities, such as with human populations, it is more difficult to quantify damage or loss, including the loss of life.86 For example, people displaced from their homes due to floods or extreme temperatures may also face emotional, psychological, physical, and social stress due to the disruption to their lives.

Risk assessments need to account for the probability or likelihood of these events occurring and the likelihood of damage. The costs associated with damage or loss to the facility or asset are often factored in as well. Yet, risk analysis differs under climate change because the environment is not static, meaning that the risk of an event occurring will shift over time. For example, what has historically been a 1 percent flood event (1-in-100 years) may now be a 1.25 percent flood event (1-in-80 years), given recent climate changes. The same event might have a 2 percent (1-in-50 years) probability of occurrence by 2050 and a 5 percent (1-in-20 years) probability of occurrence by 2100.

Similarly, the amount of damage or loss from an event may change over time as the impacts become more severe under climate change (e.g., higher floodwaters). The use of climate scenarios is one way of capturing a range of possible values for key climate conditions, such as temperatures and precipitation. The scenarios then enable planners to evaluate how different amounts of change can impact risk outcomes.

Planners must consider the cost due to damage or loss, which is more than simply the replacement or repair cost. It often includes the societal costs of losing the functionality of the asset or facility. For example, a damaged bridge will have costs associated with repair or replacement, but there will also be costs to those having to find other paths to their destinations (e.g., detour time) and to those who now have more limited options for moving people and goods.

In evaluating risk, it is important to:

- **Consider the vulnerability of different populations and ecosystems** to the predicted hazard(s) and the populations’ ability to adapt to the impacts (e.g., adaptive capacity). In adaptation planning, most effort is spent on identifying the level of exposure to different climate hazards. For example, the extent of future flooding scenarios indicates which populations, facilities, structures, and other community or environmental resources will be exposed to this hazard. How disruptive this hazard is to individuals and groups is driven by underlying social, economic, demographic, physical, and environmental factors. Considering vulnerability and associated equity impacts is critical for this stage of the planning process.

- **Identify and focus on critical community facilities and services.** FEMA’s concept of Community Lifelines are considered the most fundamental services in the community that when stabilized, enable all other aspects of society to function. Community Lifelines are also useful in identifying key infrastructure (for more on the cascading climate impacts to Community Lifelines, see Appendix A). Other institutions, including historical buildings, social or religious institutions, and unique community features (e.g., monuments, county parks), may be identified as priorities for investment or protection. Planners may consider the cascading impacts of potentially losing those services in the prioritization process and they should note that economic valuation may be insufficient to capture community concerns.

- **Identify assets in the community that are at high risk to climate-driven threats.** Focus on assets that could be vulnerable to climate-related hazards and risks, so they can be documented in the plan and factored into the adaptation actions. FEMA’s description of assets of concern for local hazard mitigation planning is a good starting point for identifying those that should be part of the adaptation planning process. As noted in the Local Mitigation Planning Policy Guide, "Assets are determined by the community and include, but are not limited to 1) people (including underserved communities and socially underserved populations), 2) structures (including facilities, lifelines and critical infrastructure), 3) systems (including networks and capabilities), 4) natural, historical, and cultural resources, and 5) activities that have value to the community."

An important component of this definition is the phrase “determined by the community.” Infrastructure networks, for example, already have criteria that indicate their importance (e.g., level of demand, provision of access to other important community activities). Experience with adaptation planning has shown that community residents can often provide important insights on which facilities and services are critical to their everyday activities. Examples of essential community facilities include hospitals and other medical facilities, police and fire stations, emergency operations centers, evacuation shelters, resilience hubs, cooling centers, cultural centers, and schools. Transportation, water, wastewater, telecommunication, and power grid networks are good examples.

---

87 For more information on Community Lifelines, see https://www.fema.gov/emergency-managers/practitioners/lifelines.

of critical infrastructure networks. Local knowledge can help identify issues and potential solutions as seen with the Jamestown S’Klallam Tribe (Washington) case study below. Note that while impacts to critical infrastructure are included, the community placed a higher priority on climate-related risks to cultural, spiritual, socioeconomic, and nutritional health.

**Case Study: Jamestown S’Klallam Tribe (Washington) Climate Change Risks**

- Higher average temperatures will generate more extreme heat events and increased heat stress for plants, animals, infrastructure, and humans.
- Water usage from the Dungeness River is already considered critical due to multiple competing uses, especially during low flow conditions in the late summer and early fall. Shifting seasonal precipitation will lead to wetter winters and drier summers; winter snowpack has decreased, and spring snowmelt occurs earlier, increasing spring flows and decreasing summer and fall flows.
- Rising sea levels will increase coastal flood risk. Furthermore, higher acidic ocean waters will make it more difficult for some organisms to build their shells, potentially affecting their survivability and the abundance of predator species.
- The Northwestern portion of the Olympic Peninsula is projected to become drier, shifting tree species away from primarily western hemlock to primarily Douglas fir and causing coincident declines in western red cedar.
- Climate change impacts human health directly (e.g., storm events) and indirectly through intermediate environmental factors (e.g., air pollution).
- Population-wide changes to tribally valued plants and animals have the potential to disrupt cultural, spiritual, socioeconomic, and nutritional health.
- Through a community-driven process, tribal members identified the following as the priority areas of concern relating to climate change:

  **Very High Priority**
  - Cedar harvests
  - Salmon, clams, and oysters
  - Shellfish biotoxins
  - Wildfires

  **High Priority**
  - Casino and Longhouse market
  - State Highway 101
  - Tribal campus water supply infrastructure

  **Medium Priority**
  - Water supply infrastructure
  - Laboratory and planning department buildings
  - Tribal wastewater infrastructure

---

Key Takeaways for Emergency Managers: Step 2

- Identify data and information sources on past extreme weather-related events.
- Lead or participate in the process of:
  - Understanding past extreme weather events and their impacts to the community, Community Lifelines, and identify lessons for the future.
  - Identifying and evaluating climate scenarios and the types of impacts and consequences these conditions may have on the community.
  - Identifying underserved population groups, as well as critical community facilities, assets, and services that could be affected by changing climatic conditions.
- Collaborate with others to provide information and outreach to the community so different groups understand the potential risks posed by climate-related hazards.

4.3. Step 3: Determine Goals and Objectives

The next step in the planning process focuses on using the information gathered during Step 2 to develop goals, objectives, and performance metrics for the climate adaptation plan. These are then used to guide the identification of the adaptation strategies and actions that the jurisdiction will choose to undertake during Step 4 of the process.

Set Goals and Objectives

Goals and objectives describe the desired outcomes of the effort and inform the steps needed to achieve them. The process of setting goals and objectives for climate adaptation planning is similar to the process used for general and emergency planning. Given that climate adaptation planning can incorporate a broad array of objectives over long timeframes, it is important to ensure that each stated objective is targeted and actionable. Equally important, the process of setting goals and objectives should incorporate a wide range of community partners, including both individuals and organizations, to ensure a high level of buy-in with the plan and investment in its implementation.

Examples of Goals and Objectives Include:

**Goal:** Reduce the exposure or sensitivity (degree to which exposure impacts the system) of critical structures, infrastructure, populations, and habitats to climate change risks.
To ensure the goals and objectives help create a more resilient community with greater adaptive capacity, it is important to develop metrics that can be used to evaluate progress. Metrics fall into two categories: process measures and outcome measures. See Table 3 for a comparison.

### Table 3: Process Measures versus Outcome Measures

<table>
<thead>
<tr>
<th>Process Measures</th>
<th>Outcome Measures</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Process measures</strong> assess adaptation efforts or operations, as well as the allocation of resources. Examples include the number of staff trained in resilience procedures, the number of systems (e.g., communication, data management, disaster response) updated for greater resilience, and the level of planning coordination across agencies or governments.⁹⁰</td>
<td><strong>Outcome measures</strong> evaluate performance under specific circumstances, often within the context of the stress or hazard for which they were designed. Examples include event response and recovery; biodiversity indicators of ecosystem conditions; measures of equity in recovery from an event or stressor; local measures of climate and environmental changes. Outcome measures may also be tied to evaluation tools used to prioritize actions (see Step 4).</td>
</tr>
</tbody>
</table>

Most climate adaptation plans require a combination of process measures and outcome measures. When developing measures, the planning team should determine which measures require the identification of a baseline (e.g., current conditions) to compare with later conditions. Additionally, performance metrics, like many parts of the plan, may need to be developed iteratively and re-evaluated after strategies have been planned. In some cases, the planning team may find it necessary to develop strategy-specific performance metrics. For a broad inventory of resilience metrics, see the National Institute of Standards and Technology's (NIST) Inventory of Community Resilience Indicators and Assessment Frameworks. For an example of goals and objectives from Hennepin County, Minnesota, see the case study below.

**Case Study: Goals and Objectives in Hennepin County’s Climate Action Plan**

In May 2021, Hennepin County, Minnesota, published a Climate Action Plan with strategies for mitigating and adapting to climate change. Below is a sample of their goals and objectives:

**Goal:** Increase the resilience of the built environment and protect natural resources.

- **Objective:** Climate risks and impacts on county buildings and infrastructure are assessed and mitigated.
- **Objective:** The county employs green and natural infrastructure to increase resiliency of the built environment, especially in areas at high-risk for localized flooding and extreme heat.

**Goal:** Protect and engage people, especially vulnerable communities.

- **Objective:** The county’s response to climate change prioritizes the protection of the most vulnerable residents and advances equitable health outcomes.
- **Objective:** Residents, businesses, and organizations pursue individual actions and support collective actions that drive systems change.

**Key Takeaways for Emergency Managers: Step 3**

- Collaborate with community partners to outline the desired outcomes of the plan and the objectives that can frame individual actions or strategies.
- Ensure that objectives are targeted, actionable, and incorporate the perspectives and priorities of the collaborative planning team established in Step 1.
- Lead or participate in the development of performance metrics that can be used to measure the effectiveness of the goals and objectives.

---

91 For more information on NIST’s Inventory of Community Resilience Indicators and Assessment Framework, see [https://data.nist.gov/od/id/mds2-2297](https://data.nist.gov/od/id/mds2-2297).

4.4. **Step 4: Develop the Plan**

Step 4 of emergency operations planning described in CPG 101 focuses on developing courses of action to accomplish goals and objectives established during Step 3. Step 4 focuses on identifying and prioritizing the strategies and actions that the jurisdiction will take to address climate-related risks, as well as the resources and information necessary to implement those actions. The outputs of this step are then used to write and review the plan in Step 5.

**Develop and Analyze Resilience Strategies and Actions**

Step 2 and Step 3 identified the community’s climate-related risks, their impacts, and the community’s goals and objectives. Using this information, the planning team now identifies strategies and actions to avoid or mitigate those risks and achieve the identified goals and objectives. This process involves not only technical staff and subject matter experts, but also includes community outreach to collect public input on strategies and actions. Adaptation plans typically include a broad range of strategies and actions; some strategies or actions may be mutually exclusive (e.g., disaster waste management or electric car charging stations along evacuation routes).

Although the identification of adaptation strategies and actions is a locally-led process, there are many resources that present information on different types of adaptation strategies. For example:

- SLTT communities now have more access to cleaner (low-carbon) materials through eligible FEMA programs, as communities rebuild or take initiatives to become more resilient. This ensures communities can help advance the clean energy economy as they confront the impacts of the climate crisis.  
  
- The U.S Climate Resilience Toolkit provides a wide-range of possible adaptation strategies and actions relating to the built environment, coasts, ecosystems, energy, food, health, marine, transportation, tribal organizations, and water. The Drought and Infrastructure - A Planning Guide can be used to anticipate and prepare for the consequences of drought on infrastructure services. The toolkit also includes filterable case studies by climate threat (or stressor), topic, resilience step, or region.

---

93 For more information on Building a Clean, Climate-Resilient Economy through FEMA’s Grant Programs, see https://www.fema.gov/grants/policy-guidance/low-carbon-goals.

The EPA’s Strategies for Climate Change Adaptation identifies strategies that can be applied to the natural environment (e.g., air, water, waste, public health). Many climate adaptation plans focus on physical (engineered) improvements to structures and infrastructure or emphasize the importance of education and raising awareness of climate-related risks. In addition to the physical improvements, ecosystem or nature-based adaptation strategies use biodiversity and ecosystems as a means of reducing climate-related risks. An example of this is extending or enhancing coastal wetlands to protect the land located behind them.

Most adaptation strategies and actions focus on achieving one or more objectives. For example, a plan might have twin objectives of reducing the sensitivity of stormwater infrastructure to extreme rainfall events and reducing biodiversity loss throughout the community. Broader use of “green” infrastructure design concepts could be an applicable adaptation strategy for both objectives.

Adaptive capacity, on the other hand, is the ability of individuals or systems (e.g., infrastructure, a community, an ecosystem) to adjust to climate stressors. One objective might be to increase the adaptive capacity of critical infrastructure. A corresponding strategy might be building redundancy into network operations so that functionality lost through damage to one portion of a network is automatically replaced with functionality from another portion of the network. Consider the pros and cons along a green to gray infrastructure continuum (See Figure 13 below).

How GREEN or GRAY should your shoreline be?

<table>

97 For more information on Understanding Living Shorelines, see https://www.fisheries.noaa.gov/insight/understanding-living-shorelines.
Different types of strategies can be used to implement adaptation actions. In some cases, existing institutional mechanisms or structures, such as changing building codes, may make implementation straightforward. Sometimes, implementation may need to be tailored to current institutional structures (e.g., government agencies, organizations), or a new structure put in place.

### Examples of Implementation Strategies

- **Legal/Regulatory**: Useful for ensuring a minimum standard of performance or condition but often difficult to use politically.

- **Market**: Includes such tools as financial incentives, grants, interest-free loans, all-hazard risk insurance, taxes and fees. Fairly flexible in implementation, but desired outcome is not guaranteed due to uncertainty in individual, household, organization, or agency behavior. Often used to create a niche market for certain types of adaptation strategies.

- **Partnerships**: Voluntary agreements or compacts among agencies and organizations to achieve desired outcomes. Effectiveness depends on the ability of participants to assign the staff and funding resources to make the partnership work. Pooled resources of participants often raise questions of appropriate contributions to the partnership.

- **Persuasion and Awareness**: Usually implemented through web-based communication and exchange capabilities, in-person outreach, newsletters and awareness campaigns. Outreach helps to develop support for plan and individual strategy implementation but rarely successful in implementation by itself.

- **Hybrid Planning**: Combination of different implementation strategies based on a systematic understanding of how the different strategies interconnect and interoperate to achieve community climate resilience.

When identifying strategies and actions, it is important to consider and document implementation needs. These needs affect strategy or action selection and prioritization. The planning team should identify or establish an entity (e.g., agency, organization) to be responsible for the implementation of each strategy or action. The team should also outline the relationships that will provide leadership in the implementation phase. This includes making sure stakeholders have 1) a common understanding of desired outcomes and how individual strategies contribute to achieving them, 2) an understanding of the timeframe for implementation of each strategy, and 3) awareness of the key stakeholders and partners who might help implement the strategy.

---

Prioritize Strategies and Actions

Once strategies have been identified, the next step is to determine which strategies and actions to prioritize. These priority strategies and actions then become the basis for the climate adaptation plan. Prioritization is driven by one primary question; which of the options best help achieve the adaptation plan goals and objectives given a range of possible climate futures? In other words, prioritization identifies robust actions that achieve optimal results across a range of climate scenarios. From an emergency management perspective, actions may include but are not limited to:

- Evacuation planning;
- Sheltering facilities;
- Floodplain management;
- Public information campaigns;
- Supply chain logistics; and
- Cooling or heating centers and resilience hubs.

Prioritization is usually based on a set of criteria that reflect the most important community concerns relating to desired plan outcomes. The planning team should determine which criteria to use with the input of whole community stakeholders. In some cases, quantitative criteria, such as monetary risk estimates or the population considered underserved to a particular hazard, are used. In other cases, the criteria could include subjective assessments of overall effectiveness or risks associated with each option. For example, some climate adaptation planning efforts use subjective values of low, medium, or high based on the collective opinions of experts, staff, decision-makers, or the general public. And in some cases, such efforts have used a combination of quantitative and qualitative assessments.

Examples (in alphabetical order) of criteria that are often found in prioritization efforts include:

- **Additional benefits**: Does the strategy or action have additional, perhaps unquantifiable, benefits beyond enhanced climate resilience for the community? All things being equal, those strategies and actions that provide additional benefits would be preferred over those that do not.

- **Benefit-cost analysis**: In some cases, it is possible to estimate the cost of implementing a particular action as well as to assign monetary values to the expected benefits of implementation. This could be done in a straightforward manner, such as measuring the benefits of reduced damage to buildings, or may require a more nuanced approach, such as assigning a monetary value to social and environmental benefits (e.g., positive health impacts). Using benefit-cost analysis examines strategies through a monetary lens, weighing whether the benefits exceed the cost. Such analyses can also be used to determine the extent to which one action is more beneficial than another.

- **Cost-effectiveness**: In many cases, the cost to implement a strategy or action can be estimated, along with the outcome, or benefit, expected from the investment. Cost-effectiveness criteria estimate the expense that is required to produce a given outcome or output. Examples include
the average dollar amount needed, per home, to harden against tropical storms; the cost to reduce a community population's vulnerability to a specific potential hazard by \( X \) percent; and the investment necessary to reduce the incidence of a serious health hazard to \( X \) percent.

- **Equity**: Assessing the equity impacts of climate adaptation strategies begins with evaluating how different demographic groups benefit or are harmed from a given action. A key question is, what individuals or community groups are reaping benefits and who is negatively affected? Special consideration should be given to historically underserved groups, such as low-income, minority, elderly, chronically sick, and mobility-impaired people and households. The equity criterion intends to allocate the benefits and costs of climate adaptation investment equitably across a community in a manner that reduces, rather than perpetuates, existing inequities.

- **Flexibility**: Given the uncertainty in the timing and scale of climate hazards and risks, many climate adaptation plans emphasize strategies and actions that can be phased in over time or whose adaptive capabilities can be easily expanded.

- **Implementation feasibility**: This criterion reflects the legal, financial, organizational, political, and social challenges associated with implementing a strategy or action. Some strategies may offer significant risk reduction potential yet face major political or social barriers. Alternatively, some strategies may be “low-hanging fruit” and able to be quickly and easily implemented.

- **Robustness**: Given the uncertainty of future climate conditions, strategies that provide resilience benefits under different scenarios are preferable over those whose benefits only occur with one possible future. This is particularly applicable to strategies or actions that mitigate current threats, hazards, or risks and provide long-term benefits at the same time. This analysis should also consider timing and the consequences of taking no action. A particular action may be significantly more costly or ineffective (e.g., conservation of key habitat) if the action is delayed.

### Identify Resource and Information Needs

After selecting strategies and actions undertaken, planners identify the resources and information needed to carry out actions of the adaptation plan. Resource requirements will vary widely depending on the strategies or actions selected and can encompass a wide range of items, such as engineering or construction equipment; site-specific analytics, including measurement or analytical tools (e.g., drones, computers); external funding; new hires or volunteers; land needs, natural resources (e.g., seeds, saplings), or habitat-specific interventions (e.g., endangered species). Resources should be listed without regard to current availability. Then, the planning team can identify what resources are currently available and what will need to be obtained moving forward.
Case Study: New Mexico’s Plan for Burying Powerlines

The 2011 Las Conchas fire was started by a downed power line in the Santa Fe National Forest. It burned more than 156,000 acres, 63 homes, and 49 additional structures with total midpoint damage estimates of $615 million. Climate projections indicate that New Mexico will further be impacted by stronger winds and drier seasons which in turn increase the risk of fires and the potential for flooding from burn scars. Buried power lines would reduce the risk of ignition as these lines are not susceptible to damage from high winds or falling trees.

After seeking funding through other means, the Los Alamos Department of Public Utilities reached out to their County’s Office of Emergency Management to see if they could partner together to fund the burying of these power lines through hazard mitigation grant dollars. Since the project was listed in the Hazard Mitigation Plan, it was a potential funding source for this proposal and it is currently being reviewed for approval.

Partnerships, such as through mutual aid agreements, are an important method for obtaining resources not readily available to a community, particularly for smaller or under-resourced communities. Identifying regional partners that either have the needed resource or have a similar need for the same resource can help cut costs and establish mutually beneficial working relationships. These partners may be governmental or non-governmental. Local businesses, for example, may be willing to provide certain resources or be willing to help fund their acquisition. External funding sources, such as federal or state grants, are another good mechanism for obtaining needed resources. For a list of emergency management funding resources, see Appendix C.

Key Takeaways for Emergency Managers: Step 4

- Lead or participate in the multi-agency and multidisciplinary process of identifying and prioritizing strategies and actions to enhance community resilience.
- Draw upon experience and local knowledge of past hazard events in the formation of adaptation strategies and actions.
- Encourage innovation in developing new strategies and actions.
- Contribute to the preparation of the climate adaptation plan by linking information relating to the local hazard mitigation plan, recent experience with climate-related hazards and community preparedness.
- Identify the physical, financial, or institutional resources and information needed to implement strategies or actions.
4.5. **Step 5: Prepare and Review the Plan**

Step 4 resulted in a set of prioritized strategies and actions for enhancing community resilience to climate related threats, hazards and risks. The next step is to prepare and review the plan. This includes writing the actual plan, leveraging the information from Steps 2, 3, and 4.

### Climate Adaptation Plans Components

- A summary of the expected climate impacts to the community and region; background on the methods and approach used to evaluate risk; the results of the local and regional risk analysis; and key threats to underserved populations and important community assets.
- Specific goals and objectives that outline the long-term desired outcomes for the community and break these goals into targeted and actionable steps.
- Strategies, actions, and responsibilities to achieve one or more objectives through targeted policy, investment, engagement, operational changes, and institutional reform.

Review of a climate adaptation plan follows a similar pattern to that for traditional planning. First, the planning team should review the plan and then make it available to other pertinent stakeholders (e.g., community organizations, local institutions, subject-matter experts, the public). Given that the adaptation plan may be the first within a jurisdiction, it may be useful to review peer community plans and use these as a source of comparison. This can help identify areas that are underdeveloped in the current draft plan, such as the rigor of the performance metrics. Similar to the process in *CPG 101*, three criteria can be used when evaluating the plan:

- **Adequacy**: Does the scope of the plan include the primary (and potential secondary) climate threats to the community? Do the plan’s goals, objectives, strategies, and actions propose a course for mitigating climate-related risk? Are the plan’s assumptions (e.g., climate science) valid?
- **Feasibility**: Are the organizations or agencies capable of accomplishing assigned tasks, either with available resources or with reasonable expectation of securing necessary resources? Are the timeline and project size sufficient to meet the stated need and practical? Can coordination with necessary stakeholders or government agencies be secured?
- **Acceptability**: Do the adaptation strategies meet the threats posed by climate change? Are the strategies and objectives designed to be equitable and achieve social as well as physical resilience? Is the plan consistent with the law and with relevant guidance?
These criteria can be used to evaluate the plan’s goals, objectives, and strategies, along with how they are coordinated and allocated across agencies or stakeholders. Moreover, they can be useful in assessing whether the resources needed to implement a strategy or action are immediately available or whether outside funding sources will need to be pursued. The Tompkins County, New York case study below provides an example of a final climate adaptation chapter in a comprehensive plan.

**Case Study: Tompkins County, New York Climate Adaptation Strategy**

The [Tompkins County Comprehensive Plan](https://tompkinscountyny.gov/planning/climate-adaptation) includes a chapter on adaptation. This chapter indicates that it is the policy of Tompkins County to:

- Maintain floodways and limit floodplain development to reduce damages from flooding;
- Improve connectivity of open space to prevent fragmentation of ecosystems;
- Promote adaptation measures that lessen climate impacts on the local economy;
- Encourage actions that protect underserved populations from climate change impacts; and
- Prepare for community recovery in the event of disaster.

The Tompkins County Department of Planning and Sustainability also developed a Resiliency and Recovery Plan to help reduce the risks associated with hazards and the changing climate. The plan lays a foundation for collaborative action with each of the municipalities in Tompkins County and a broad group of stakeholders. It addresses four critical areas from the County’s Hazard Mitigation Plan: Flooding, Drought, Debris Management, and Economic Recovery.

**Key Takeaways for Emergency Managers: Step 5**

- Lead or participate in multi-agency efforts to write and review the climate adaptation plan.
- Help identify the roles and responsibilities of stakeholders to carry out the plan.
- Provide information on possible funding sources to implement planned strategies and actions.

---

4.6. **Step 6: Implement and Maintain the Plan**

Once reviewed, approved, and released, implementation and maintenance of the plan begins. This step focuses on monitoring and evaluating the performance of the plan, updating the plan as needed, and mainstreaming adaptation planning in the community.

Implementation is a long-term process. Some tasks will occur soon while other strategies are updated and executed over a course of years. The callout box below outlines key considerations for implementation.

**Considerations When Implementing and Maintaining the Plan**

- Assigning sub-tasks to individuals, groups, or organizations;
- Obtaining the financial resources to pay for implementation;
- Developing interorganizational partnerships and agreements when implementation includes multiple players;
- Developing a constituency for the different actions among key stakeholders and the public; and
- Linking assigned actions to the decision-making processes of that organization(s).

As with most planning efforts, climate adaptation planning is an iterative process that entails regular reviews and adjustments. Updates are particularly important for climate adaptation planning where advances in climate science occur constantly, new data sources become available, intervening extreme weather events provide new information on the severity and extent of the resulting damage, and the communities themselves can change in various ways.

**Monitor and Evaluate Performance**

Monitoring and evaluating the performance of the plan and regularly reviewing the underlying assumptions is an important part of assessing whether a community’s climate adaptation plan is still relevant and meeting the desired outcomes. Monitoring should address the criteria in the performance metrics designed in **Step 3** but should also ensure the underlying assumptions that led to the selection of adaptation strategies are still valid. For example, collecting data on recently implemented NBS to verify if there was a reduction to frequently flooded areas. This information
provides an important feedback loop to determine whether adjustments to the plan are needed. Analyzing individual strategy effectiveness could lead to minor adjustments or they might suggest a rethinking of the entire strategy.

Ideally, an agency or multi-agency structure would be designated to lead the implementation, monitoring, evaluation, and revision of the plan. For some communities, this may be the emergency management agency, who is already monitoring for hazard mitigation plans and THIRAs, as well as evaluating exercises and real-world events through after-action reports.

**Update the Goals, Objectives, and Metrics of the Plan**

Revising or updating a climate adaptation plan can occur periodically, such as every five years or when circumstances dictate, or in the aftermath of a particularly severe extreme weather event. The plan should establish this process and the update should be undertaken by the same (emergency management) agency or a multi-agency structure that coordinates monitoring and evaluation. Updating the plan might include altering how a goal or objective is being implemented, or it may involve altering the strategy itself. In the latter instance, strategy changes should be vetted with leadership to ensure that their implementation is feasible. Even evaluating what strategies and implementation practices have been ineffective is a useful learning exercise for future planning or potential funding efforts.

### Training and Exercise the Plan

Trainings and exercises provide opportunities to stay up to date with current climate science and tools as well as a chance to learn about best practices used by other jurisdictions.

FEMA’s [Exercise Starter Kits](https://www.fema.gov/long-term-community-resilience-exercise-resource-guide) and [Long-Term Community Resilience Exercise Resource Guide](https://www.fema.gov/long-term-community-resilience-exercise-resource-guide) are a "one-stop-shops" for any jurisdiction or organization looking to conduct a climate-focused exercises. For more information, see [Appendix D](#).

### Factors for Updating Climate Plans

- New information on climate science
- New data and tools for vulnerability and risk analysis
- Experience with recent extreme weather events
- Community development patterns
- Population characteristics
- Community values
- Updates to other community plans and strategies
- Addition of new staff and expertise
- New technology innovations that change demand and service patterns
- Laws and regulations
Case Study: New Orleans, Louisiana Tree Planting for Canopy Cover

Over the last 20 years, the City of New Orleans has seen considerable tree canopy loss due to storms and hurricanes such as Katrina (2005) and Ida (2021). The lack of canopy cover contributes to the urban heat island effect, causing parts of the City to be nearly nine degrees hotter than others. These heat islands disproportionately affect lower-income areas.

The City worked with the nonprofit SOUL (Sustaining Our Urban Landscape) to develop a Reforestation Plan to reverse this canopy loss and prioritize work in historically disadvantaged neighborhoods. Over time, these trees will decrease extreme heat and reduce street flooding by increasing water absorption. The city has used a combination of public and private grants to begin planting the trees and training the urban forestry workforce to maintain them during drier and warmer periods, which are becoming more frequent with climate change.

New Orleans has a Climate Action Goal to plant 40,000 trees by 2030. With the Hazard Mitigation Plan due for updates in 2025, the City will look to benchmark the progress that has been made towards the 2030 goal. Between 2017-2023, 17,914 trees have been planted.

Figure 14: Volunteers planting a tree in the Algiers Neighborhood of New Orleans
Source: [https://soulnola.org/reforestationplan/](https://soulnola.org/reforestationplan/).

Key Takeaways for Emergency Managers: Step 6

- Participate in multi-agency efforts to raise community awareness and implement adaptation plan recommendations.
- Collect data and information on climate-related hazards to inform future plan updates and monitor the performance of implemented strategies.
- Lead or participate in evaluating whether implemented and recommended adaptation strategies are still appropriate given changing environmental conditions.
- Coordinate changes in the local hazard mitigation plan with the strategies of the adaptation plan and continue to monitor and evaluate overtime.
5. Conclusion

The purpose of this guide is to help SLTT emergency managers incorporate climate adaptation into emergency management planning efforts. The six-step planning process presented here is broadly applicable to many different climate adaptation planning contexts, yet the individual actions and planning roles are designed to help SLTT emergency managers both lead and support climate adaptation planning. Emergency managers’ experience identifying and mitigating hazardous threats and vulnerabilities can be of great use in planning for long-term community resilience and adaptation even as climate change continues to be a “risk multiplier.”

Many of the initial steps in the climate adaptation planning process presented here are similar to those used in CPG 101; however, as described earlier, there are several key differences:

1) While planning and preparing for emergencies always involves uncertainties and a need to assess risks, climate-related threats magnify this uncertainty due to an inability to predict future emissions and climate mitigation policies. Therefore, adaptation planning should address multiple climate scenarios (e.g., intermediate emissions, high emissions) and investigate which projections are most applicable to the community.

2) Actions to address the changing climate, as well as knowledge of climate science and vulnerabilities, are constantly evolving. Planning for climate-resilient communities should become an iterative process to ensure that strategies and plan priorities reflect the best information available. Furthermore, exercising, monitoring, and adjustment of plan implementations ought to occur regularly to optimize the effectiveness of adaptive actions. Changing economic and demographic considerations may also necessitate adjustments to the plan or its implementation.

3) Creating and sustaining a climate-resilient community is most feasible when adaptive responses are incorporated into all aspects of community planning and decision-making. Moreover, the equity implications of both climate impacts and responses should be an important part of the discussion both in creating the adaptation plan and in developing other community plans and policies. A thorough and iterative planning process, along with strong community partnerships that draw on a range of social and technical expertise, will create a strong foundation for building and sustaining a climate-resilient community.
Appendix A: Climate Impacts on Emergency Response and Recovery Planning

The climate hazards that regions and communities are occasionally exposed to will become more frequent, severe, and afflict new areas. Some of the most damaging events have been the result of combined weather phenomena, producing multiple hazards simultaneously. Hurricane Sandy, for example, was the combined result of a nor’easter and a hurricane, producing devastating results. Natural hazards can also co-occur with other phenomena amplifying the overall risk. In 2021, Louisiana was hit by the second-most damaging hurricane in the state’s history, Hurricane Ida, in the midst of the COVID-19 pandemic, putting greater stress on the area’s hospitals, among other social and economic impacts of the pandemic. Figure A-1 highlights hazards that may have direct (or primary) and cascading (or secondary) impacts. Weather extremes will also likely directly impact or cause cascading impacts to response planning and into recovery.

Figure A-1: Climate Hazards and Their Direct and Cascading Impacts
Using the eight Community Lifelines and six Recovery Support Functions (RSF), below is a bulleted list of direct or cascading impacts from an emergency response and recovery perspective.

**Safety and Security Lifeline**
- An anticipated increase in climate-related events may strain state, local, tribal, and territorial (SLTT) response resources and capacities, resulting in increased requests for federal support.
- Decreased water volumes in remote streams and ponds may hamper firefighting capabilities.
- Persons with disabilities and those who live in rural areas have restricted (or lack) access to government services.
- Under-resourced populations and communities may lack access to capital that could help support resilience investments.

**Food, Hydration, Shelter Lifeline**
- Temperature and precipitation extremes may affect water quality and availability, agricultural productivity, ecosystems, and species.
- Thawing permafrost may lead to unsafe food storage and preservation.
- People with disabilities have high rates of illness, injuries, or death during extreme events, as cognitive, hearing, physical, and mobility impairments may impede their safe evacuation.
- Sheltering needs may overwhelm SLTT capacities due to increases in climate-related events. Federal support may be required for the provision of additional sheltering and/or the relocation of impacted populations to unaffected areas.
- Wrap-around services may need to be provided for survivors waiting to access aid sites to ensure their health and well-being (e.g., moving water distribution to shaded areas in extreme heat scenarios). Pre-identified aid sites may need to be reevaluated to ensure protection for those awaiting access.

---

Health and Medical Lifeline

- More frequent and severe heat waves will lead to more heat-related illnesses and deaths.
- Changes in the timing and lengths of the seasons may cause shifts in the geographic areas where disease-carrying insects such as mosquitoes, ticks, and fleas typically transmit West Nile Virus, dengue fever, Lyme disease, malaria, and other diseases.
- Increasing temperatures may cause degradation of air quality, exacerbating health conditions such as heart disease.
- Increased plant growing seasons may increase pollen exposure. A greater number of severe storms will also increase mold exposures. Increased temperatures and wildfire risk will further lead to more air pollution. All of these changes may worsen lung diseases and other health problems.
- Extreme weather events are associated with an increased risk of food- and water-borne illnesses, as sanitation services, hygiene measures, and safe food and water supplies are often compromised after such events.
- An increase in the loss of patient medications is expected due to a larger number of power outages and subsequent lack of refrigeration capabilities.
- Increasing frequency and severity of wildland fires will reduce ambient air quality causing increases in respiratory distress, especially among those with respiratory ailments, children, and the elderly.

Energy Lifeline

- Power transmission line capacity will decline at higher temperatures, reducing power availability; extreme heat may also cause powerlines to droop.¹⁰³
- Extreme temperatures increase demand for cooling and heating capabilities, which may result in electricity shortfalls.
- Climate-related incidents, such as increases in extreme heat and wildfires, will increase the likelihood of public safety power shutoffs, limiting access to power.
- Extreme flooding or severe weather may threaten energy infrastructure.
- Underserved communities are historically the last communities to have their utilities restored.

Communications Lifeline

- Extreme flooding or severe weather may impact communications infrastructure due to damage or loss of power.
- Buried fiber optic cables and nodes, which provide communications and internet services, are at risk of failure due to sea level rise and flooding. Similar fiber optic cable issues may occur above ground due to high winds associated with hurricanes, derechos, and other extreme weather phenomena.

events. Communications nodes are often clustered at low elevations around dense populations. Fiber buried on land is water- and weather-resistant but is not designed to be submerged.\textsuperscript{104}

- Persons with access and functional needs will require the need of assistive technology or other communication support to receive information and how to respond during a disaster.

**Transportation Lifeline**

- Extreme heat can warp railways, impacting rail operations, and can cause paved surfaces to buckle, disrupting transit and making it difficult for airplanes to take off.\textsuperscript{105}
- Higher winds and wildland fires may disrupt air traffic.
- An increase in flooding or weather events that result in the accumulation of debris will impact transportation routes.
- More than 60,000 miles of roads and bridges in coastal areas are at risk of flooding from climate-change-related sea level rise.\textsuperscript{106}
- Permafrost thaw may reduce the viability of roads made of ice and snow and damage transportation infrastructure due to ground sinking.\textsuperscript{107}
- Compounding climate-related weather events that impact the transportation system could severely impact supply chains due to worker attrition or flooded routes. Disruptions to supply chains will impact operations, logistics, and management activities for response and recovery.
- The development of community-specific distribution management plans that highlight vulnerable transportation infrastructure and alternate commodity points of distribution should be supported.
- Disruptions to transportation infrastructure can affect communities and their access to food, healthcare systems, and social services.

**Hazardous Materials Lifeline**

- Increased climate-related weather events may result in larger quantities of waste materials that require processing. This may lead to increased greenhouse gas (GHG) emissions from waste management activities as well as insufficient capacities for handling surges in the necessary recycling, treatment, and disposal processes for the waste generated.\textsuperscript{108}
- Extreme weather events may impact industrial facilities resulting in contamination of surrounding communities (often low-income communities) requiring permanent evacuation and exposure to hazardous materials.
- Severe storms and heavy flooding are likely to result in industrial process disruptions which could result in autocatalytic reactions, explosions, and discharges when a facility is not able to

store chemicals at the proper temperature on alternate power sources or properly shut down continuous flow process.

- Low-income communities are often disproportionately impacted by hazardous materials events due to their proximity to hazardous facilities or transportation routes. These communities may also have limited resources to respond to and recover from such events.
- Indigenous communities who practice subsistence farming and fishing are particularly vulnerable to the impacts of hazardous materials.

**Water Systems Lifeline**

- Thawing permafrost may lead to the deterioration of reservoirs and impoundments that rely on the existence of permafrost for wastewater containment.
- The intersection of flooding and warmer weather may cause bacterial growth in local water sources, leading to health concerns (e.g., toxic algae blooms).
- Aging water infrastructure threatens the quality of drinking water. This infrastructure is unprepared to cope with risks worsened by climate change, including flooding, drought, and waterborne diseases.
- In coastal and island areas, aquifers are threatened by saltwater intrusion, which can harm water infrastructure and make groundwater not drinkable.

**Community Assistance Recovery Support Function**

- Equity issues regarding illiteracy should be taken into consideration when conducting community engagement and training.
- Community assistance efforts and climate considerations should be incorporated into long-term recovery planning support strategies.

**Economic Recovery Support Function**

- Labor hours lost by weather-exposed workers due to high temperature days.\(^{109}\) There is also an equity consideration on the demographics of weather-exposed workers.
- Increase in property damage and business income losses due to increasing frequency and intensity of climate-related hazards.
- The displacement of socially vulnerable and underserved people may often coincide with the displacement of essential, front-line workers who are the foundation of a community’s economy.

**Health and Social Services Recovery Support Function**

- Individuals are at higher risk of developing chronic illnesses such as asthma, or fatalities from cancer, residing in areas with higher counts of particulate air pollution.\(^{110}\)

---

Climate-related disasters can drive higher incidence of mental and behavioral health issues, post-traumatic stress disorder, and substance abuse.111

Housing Recovery Support Function

- Temporary housing and sheltering will continue to be a prominent and challenging aspect of disaster recovery.

Infrastructure Systems Recovery Support Function

- Projects should leverage resilience funding support for projects that adhere to consensus-based building codes and standards for low-carbon materials.112
- Recovery-funded grant projects should emphasize mitigation measures (e.g., through the Hazard Mitigation Grant Program [HMGP] and 406 Mitigation funding) that support risk reduction actions, climate adaptation actions, and nature-based or green infrastructure solutions.
- Benefit-cost calculations should be streamlined for hazard mitigation solutions that are local, sustainable, and nature based, when possible, to enable better alignment with grant obligations and planning timelines.

Natural and Cultural Resources Recovery Support Function

- Anticipated increase in the frequency and intensity of weather events will pose a heightened risk to the protection of cultural heritage resources.

---

Appendix B: Climate Data and Mapping Applications

- **Atlas of the 5th National Climate Assessment**: The Atlas provides climate projections, interactive maps, and acts as an extension for the data provided in the 5th National Climate Assessment. The Atlas also provides map comparison options and plain-language explanations of each map.

- **Climate Risk and Resilience Portal (ClimRR)**: A public-private partnership that represents the newest developing climate science modeling. The ClimRR National Map Explorer allows users to view over 100 different climate visualizations at mid- and end-of-century in an interactive map and the ClimRR Local Climate Summary provides users with a snapshot of climate projections for a chosen location.

- **Climate Mapping for Resilience and Adaptation (CMRA)**: CMRA combines currently available federal datasets to create a climate risk information tool that also includes grant finance opportunities and policy information. This tool is a community-focused, user-friendly model that provides high-level trend information for SLTT communities. Viewers can use real-time maps showing where climate-related hazards are currently happening.

- **Climate Explorer**: The Climate Explorer offers graphs, maps, and data downloads of observed and projected climate variables for every county in the United States (U.S.). For the contiguous U.S., the tool shows projected conditions for two possible futures: one in which humans make a moderate attempt to reduce global GHG emissions, and one in which human GHG emissions continue increasing through 2100.

- **Creating Resilient Water Utilities Climate Data Maps**: The Creating Resilient Water Utilities Climate Data Maps combine complex climate and environmental data into usable formats and can help identify climate risks. Maps can be created to show scenario-based climate projections for temperature, precipitation, extreme storms, extreme heat, and sea level rise. Additional maps show the historical and projected changes in river and stream flows, coastal storm surge, and wildfire trends and at-risk communities.

- **Drought.gov**: The National Integrated Drought Information System is a multi-agency partnership that coordinates drought monitoring, forecasting, planning, and information at national and SLTT levels.

- **Grant Equity Threshold Tool (GETT)**: The GETT provides information about areas designated as disadvantaged in the Climate and Economic Justice Screening Tool (CEJST), included in the

---

113 For more information on the Atlas of 5th National Climate Assessment, see https://atlas.globalchange.gov/.
114 For more information on ClimRR, see https://climrr.anl.gov.
115 For more information on CMRA, see https://resilience.climate.gov/.
116 For more information on the Climate Explorer, see https://toolkit.climate.gov/tool/climate-explorer-0.
117 For more information on Creating Resilient Water Utilities, see https://www.epa.gov/crwu.
118 For more information on Drought.gov, see https://www.drought.gov/.
119 For more information on the GETT, see https://rapt-fema.hub.arcgis.com/pages/gett.
Climate Adaptation Planning: Guidance for Emergency Managers

Community Disaster Resilience Zone (CDRZ) Act, and binned by FEMA’s Community Resilience Challenges Index (CRCI). The GETT helps grant applicants demonstrate how potential geographic areas benefit by focusing efforts on disadvantaged communities and Tribal Lands.

- **Heat.gov:** The National Integrated Heat Health Information System is a multi-agency partnership that develops and provides actionable, science-based information to help protect people from heat. It serves as the premier source of heat and health information for the nation to reduce the health, economic, and infrastructural impacts of extreme heat.

- **National Risk Index (NRI) for Natural Hazards:** The NRI is an online mapping application from FEMA that identifies communities most at risk to eighteen natural hazards. This application visualizes natural hazards risk metrics and includes data about expected annual losses from natural hazards, social vulnerability, and community resilience.

- **Resilience Analysis and Planning Tool (RAPT):** A Geographic Information System planning tool to inform strategies for emergency management. RAPT includes over 100 preloaded layers including FEMA’s Community Resilience Index, Census demographic data, infrastructure, live weather, hazards, National Oceanic and Atmospheric Administration (NOAA) sea level rise projections, and ClimRR future conditions data.

- **Sea Level Analysis Tool:** The U.S. Army Corps of Engineers’ Sea Level Analysis Tool helps visualize observed sea level data, compare observations to projected sea level change, and estimate when tidal and extreme water levels will intersect with elevation thresholds related to local infrastructure. This data can help planners to better understand their local risk based on various scenarios.

- **Sea Level Rise Viewer:** NOAA’s Sea Level Rise Viewer is a mapping tool that helps visualize community-level impacts from coastal flooding or sea level rise up to 10 feet above average high tides. This tool provides photographic simulations of how flooding might impact local landmarks as well as data-related to water depth, connectivity, flood frequency, socio-economic vulnerability, wetland loss and migration, and mapping confidence.

120 For more information on CDRZ, see [https://www.fema.gov/partnerships/community-disaster-resilience-zones](https://www.fema.gov/partnerships/community-disaster-resilience-zones).

122 For more information on Heat.gov, see [https://www.heat.gov/](https://www.heat.gov/).

124 For more information on RAPT, see [http://fema.gov/rapt](http://fema.gov/rapt).

125 For more information on the Sea Level Analysis Tool, see [https://climate.sec.usace.army.mil/slat/](https://climate.sec.usace.army.mil/slat/).

126 For more information on the Sea Level Rise Viewer, see [https://coast.noaa.gov/digitalcoast/tools/slr.html](https://coast.noaa.gov/digitalcoast/tools/slr.html).
Appendix C: Financing Climate Adaptation and Mitigation

Policies, plans, and strategies to mitigate climate risks are of limited use if they are not adequately funded and resourced. The Federal government, SLTT governments, regional planning bodies, the private sector, and philanthropic organizations regularly provide funding for climate-related risk mitigation projects. Savvy planners can make use of many existing programs to support climate-related risk mitigation activities even if the programs do not exist to specifically combat climate-related risks. For instance, many federal grant dollars to upgrade infrastructure or mitigate natural hazards (most of which are influenced by climate change) can be used to achieve a variety of objectives including climate-related risk mitigation. The Funding Strategies for Flood Mitigation handout depicts funding sources for climate-related risk mitigation and resilience-building activities. Perhaps most important, thinking with a climate-resilient mindset can help planners find creative funding sources for climate-related risk mitigation activities.

The remainder of this appendix reviews programs that provide funding that may often be used to mitigate climate-related risks. This list is not comprehensive as does not include all-hazard risk transfer activities which play an important role in economic recovery and climate resiliency. Many other programs and funding sources exist and the following call out box provides some useful overview guides.

Funding and Financial Management Resources

- **Disaster Financial Management Guide**: Helps SLTT jurisdictions establish and implement sound disaster financial management practices.
- **U.S. Climate Resilience Toolkit**: Provides a range of government entities and private foundations offering financial and technical resources to advance local adaptation and mitigation efforts in the U.S.
- **The Institute for Local Government, Budgeting and Financial Management**: Provides access to numerous resources and case stories for engaging the public in the budgeting process, as well as a repository of budgeting and finance forms.
- **The Grants Learning Center**: Allows users to explore available federal grants and financial assistance, learn about the laws and regulations for awards, examine grant eligibility, explore grant registration and management tools, and more.
- **The Ready-to-Fund Resilience Toolkit**: Helps increase climate resilience and create thriving, just, and equitable communities by securing funding and finance for the physical and social infrastructure necessary.

Annual Program Funding Provided by Federal Agencies

This section details annual program funding from primarily federal sources. Several federal programs provide annual mitigation or mitigation-related funding to SLTT governments. The requirements for
participation, eligibility, cost share, performance periods, acceptable uses of funds and other details vary from program to program. This section highlights some key programs that may support climate adaptation and mitigation activities. Planners should consult program-specific guidance to determine if each program can support a community’s needs.

FEDERAL EMERGENCY MANAGEMENT AGENCY (FEMA) PROGRAMS

FEMA grant funds are available for pre- and post- emergency or disaster related projects. Certain non-emergency FEMA funding requires communities have an approved hazard mitigation plan in order to be eligible to apply. Some climate related FEMA resources are highlighted below:

**Building Resilient Infrastructure and Communities (BRIC)**

FEMA’s BRIC program funds capability- and capacity-building activities such as mitigation planning and mitigation projects that directly impact the natural and built environment. BRIC aims to deliver 40 percent of its overall benefits to disadvantaged communities that are marginalized, overburdened by pollution and underserved.

For communities and Tribal Nations with limited resources, the BRIC non-financial Direct Technical Assistance is available. This assistance, provided for up to 36 months, helps local and tribal jurisdictions to reduce disaster damage, build community resilience, and sustain successful mitigation programs. The wide-ranging Direct Technical Assistance initiative includes climate risk assessments, community engagement, partnership building, hazard mitigation and climate adaptation planning.

**Flood Mitigation Assistance (FMA)**

FEMA’s FMA Grant is focused on reducing or eliminating repetitive flood damage to buildings insured by the National Flood Insurance Program through mitigation planning and projects. FMA aims to deliver 40 percent of its overall benefits to disadvantaged communities that are marginalized, overburdened by pollution and underserved.

**Safeguarding Tomorrow Through Ongoing Risk Mitigation Program**

The Safeguarding Tomorrow Through Ongoing Risk Mitigation Program is a capital loan program, similar to the Clean Water Act revolving loan fund, that allows grant recipients to provide loans for zoning and land-use planning. Communities must contribute funds to be eligible; they will receive a reduced interest rate to undertake projects. Interested communities should consult their State Hazard Mitigation Officer about upcoming training and webinars.

---

127 For more information on FEMA grants, see [https://www.fema.gov/grants](https://www.fema.gov/grants).

128 For more information on mitigation planning grant requirements, see [https://www.fema.gov/emergency-managers/risk-management/hazard-mitigation-planning/requirements](https://www.fema.gov/emergency-managers/risk-management/hazard-mitigation-planning/requirements).
Regional Catastrophic Preparedness Grant Program

FEMA’s Regional Catastrophic Preparedness Grant Program supports the building of core capabilities essential to achieving the National Preparedness Goal of a secure and resilient nation by providing resources to fill known capability gaps in housing, logistics, and supply chain management in order to encouraging innovative regional solutions to issues related to catastrophic incidents and building on existing regional efforts.

Rehabilitation of High Hazard Potential Dam (HHPD) Grant Program

FEMA’s Rehabilitation of High Hazard Potential Dam (HHPD) grant program provides technical, planning, design, and construction assistance in the form of grants for rehabilitating eligible high hazard potential dams. High hazard potential is classification standard for any dam whose failure or mis-operation will cause loss of human life and significant property destruction. A state or territory with an enacted dam safety program, the State Administrative Agency, or an equivalent state agency, is eligible for the grant.

DEPARTMENT OF ENERGY (DOE) PROGRAMS

Resilient and Efficient Codes Implementation

Resilient and Efficient Codes Implementation grants provide funding for projects that support updating building energy codes as they transition to clean energy, empower workers, support resilience, and advance environmental justice (EJ).

DEPARTMENT OF HEALTH AND HUMAN SERVICES (HHS) PROGRAMS

Low Income Home Energy Assistance Program

HHS offers the Low Income Home Energy Assistance Program to mitigate extreme heat impacts by providing funding to grant recipients for cooling assistance, summer crisis assistance, year-round crisis assistance, and weatherization. In addition, it provides federally funded assistance to reduce the costs associated with home energy bills.

DEPARTMENT OF HOUSING AND URBAN DEVELOPMENT (HUD) PROGRAMS

Community Development Block Grant (CDBG)

HUD’s CDBG program supports the development of stronger and more resilient communities. Investment support may include infrastructure, economic development projects, public facilities installation, community centers, housing rehabilitation, public services, and clearance or acquisition. The CDBG program also includes targeted funding for post-disaster recovery and hazard mitigation.\(^\text{129}\)

\(^{129}\) HUD also provides eligible grantees with direct grants for use in developing Indian and Alaska Native communities through the Indian CDBG. For more information on this grant and other tribal specific federal funding opportunities, see https://www.hud.gov/program_offices/public_indian_housing/ih/tribal_climate_resilience_and_adaptation_funding.
Climate Adaptation Planning: Guidance for Emergency Managers

DEPARTMENT OF TRANSPORTATION (DOT) PROGRAMS

Promoting Resilient Operations for Transformative, Efficient, and Cost-saving Transportation (PROTECT) Program
The PROTECT program supports eligible grant recipients by increasing the resilience of their transportation system. Eligible projects include evacuation routes, coastal resilience, making existing infrastructure more resilient or efforts to move infrastructure to nearby locations that are not continuously impacted by extreme weather and natural disasters.

DOT Thriving Communities Program
The Thriving Communities Program aims to ensure that disadvantaged communities adversely or disproportionately affected by environmental, climate, and human health policy outcomes have the technical tools and organizational capacity to compete for federal aid and deliver quality infrastructure projects that enable their communities and neighborhoods to thrive.

Rebuilding American Infrastructure with Sustainability and Equity (RAISE) Grant Program
The RAISE Grant program provides an opportunity to obtain funding to build and repair road, rail, transit, and port projects. RAISE grants are eligible to a wide-range of applicants, including special purpose districts and transit agencies, along with traditional SLTT governments. Funding is split between urban and rural areas.

ENVIRONMENTAL PROTECTION AGENCY (EPA) PROGRAMS

Environmental Justice Thriving Communities Grantmaking
The Environmental Justice Thriving Communities Grantmaking Program is a competition to select multiple Grantmakers around the nation to reduce barriers to the federal grants application process communities face and increase the efficiency of the awards process for EJ grants.

Wildfire Smoke Preparedness in Community Buildings
The EPA’s Wildfire Smoke Preparedness in Community Buildings Grant Program supports enhancing wildfire smoke preparedness in community buildings. The program provides grants and cooperative agreements to states, federally-recognized tribes, public pre-schools, local educational agencies, and nonprofit organizations for the assessment, prevention, control, or abatement of wildfire smoke in community buildings.

NATIONAL OCEANIC AND ATMOSPHERIC ADMINISTRATION (NOAA) PROGRAMS

Climate Resilience Funding
NOAA maintains a list of Climate Resilience Funding Opportunities. While not comprehensive, this website is regularly updated with funding opportunities that may support climate mitigation and resilience-building activities for SLTT governments.
UNITED STATES DEPARTMENT OF AGRICULTURE (USDA) PROGRAMS

Disaster Assistance Programs
USDA offers disaster assistance through the Emergency Watershed Protection Program, Farm Service Agency, and Rural Development to help farmers, natural resource managers, and rural communities manage risk, protect their operations, and recover from the impact of natural disasters. The Disaster Assistance Discovery Tool helps those impacted by natural disasters navigate to the resources and assistance they need to access many of these programs.

Natural Resources Conservation Services
The Natural Resources Conservation Service offers a variety of programs, services, resources, and tools to help conservation programs. Financial assistance and one-on-one technical support is also available for conservation programs that directly support climate-smart agriculture and forestry including the Environmental Quality Incentives Program, Conservation Stewardship Program, Agricultural Conservation Easement Program, and Conservation Technical Assistance.

The Community Wildfire Defense Grant Program
The Community Wildfire Defense Program is intended to help at-risk local communities and tribes; plan for and reduce the risk of wildfire. This program prioritizes at-risk communities in an area identified as having high or very high wildfire hazard potential, are low-income, or have been impacted by a severe disaster that affects the risk of wildfire. Additional Federal Wildfire Grant Resources (e.g., training grants, mitigation grants, conservation funding, and restoration funding) across USDA and FEMA can further support community-led efforts to prepare for wildfire.

Urban and Community Forestry Program
The Urban and Community Forestry Program provides funding to support urban tree planting, urban forest planning and management, and related activities, particularly in disadvantaged communities.
The Bipartisan Infrastructure Law (BIL) and Inflation Reduction Act (IRA)

The Bipartisan Infrastructure Law (BIL) of 2021 and Inflation Reduction Act (IRA) of 2022 marked two pieces of landmark legislation that provide unique funding opportunities for clean energy, climate adaptation, infrastructure resilience, environmental justice, and much more. Funding opportunities for several federal agencies are listed below with agency specific links, though many more can be found using the BIL Guidebook and IRA Guidebook.

- The Department of Interior received nearly $35 billion in combined BIL and IRA funding. Funding is available for ecosystem restoration, drought mitigation, landscape conservation, and includes targeted funding ($13 billion) for Tribal communities.

- EPA programs received nearly $10 billion in combined funding from the BIL and IRA. Funding is available for projects to mitigate GHG emissions, reduce climate pollution impacts, and advance environmental justice initiatives.

- FEMA programs received $6.8 billion in funding from the BIL, with funding allocated to BRIC, FMA, Dam Safety, and other grant programs. The IRA provides financial assistance for investments in low-carbon materials, which is available through FEMA’s Public Assistance, HMGP, and BRIC programs.

- Health and Human Services created the Quickfinder for Leveraging the IRA for the Health Sector to help the health sector identify grants, loans, and tax credits that can be used to fund resilience and renewable infrastructure.

- NOAA programs received over $6 billion in funding from the BIL and IRA. Some highlights include: $1.47 billion in funding for coastal resilience (Climate-Ready Coasts); $592 million for the protection of fisheries; and $575 million for the Climate Resilience Regional Challenge.

- The USDA was allocated significant funding through the BIL and IRA for climate and energy programs, including wildfire risk and flood prevention.

Post-Disaster Funding Provided by Federal Agencies

This section details post-disaster program funding from federal sources. FEMA operates several post-disaster recovery and mitigation programs that provide an opportunity for communities to address climate mitigation and resilience building.

FEMA POST-DISASTER FUNDING

Public Assistance (PA) Program

FEMA’s PA program provides supplemental federal grant assistance for debris removal, emergency protective measures, and the restoration of disaster-damaged, publicly owned facilities and specific facilities of certain private nonprofit organizations. The PA program also encourages protection of
these damaged facilities from future incidents by providing assistance for hazard mitigation measures. Potential applicants can apply within 30 days following a Presidential disaster declaration. FEMA’s PA funding will cover no less than 75 percent of the project’s cost.

**Hazard Mitigation Grant Program (HMGP)**

FEMA’s [HMGP](#) provides funding to SLTT governments to rebuild in a way that reduces, or mitigates, future disaster losses in their communities. HMGP funding can be used for mitigation planning, post-disaster code adoption and enforcement, and mitigation projects that address any natural hazard. The amount of HMGP funding available to a state, tribe, or territory is based on the estimated total federal assistance provided under a Presidential Disaster Declaration.

**HMGP Post-Fire Program**

The [HMGP Post-Fire program](#) is available to states, tribes, and territories affected by fires that result in a Fire Management Assistance Grant (FMAG). FEMA determines annually how much funding will be available based on a rolling 10-year national average of assistance provided under FMAG declarations and determines an allocation to affected states, tribes, and territories. FEMA also sets the funding priorities, with the highest priority being wildfire and post-wildfire mitigation activities such as defensible space, erosion control and slope failure prevention.

**DOT POST-DISASTER FUNDING**

**Federal Highway Administration (FHWA) Emergency Relief (ER) Program**

FHWA administers the [ER Program](#) for emergency repair or reconstruction projects on the Federal-aid highway system needed as a result of natural disasters or catastrophic failures from an external cause. The damage to highways must be severe, occur over a wide area, and result in unusually high expenses to the highway agency. ER funds may be used on repairs that improve the long-term resilience of the Federal-aid highways, if the design is consistent with current standards, or the State DOT demonstrates that the resilience feature is economically justified to prevent future recurring damage.
Case Study: City of Tucson, Arizona Using Federal Funds

Extreme heat is the number one weather-related cause of death in Arizona. The city of Tucson has been in an extreme heat state of emergency since 2020. The Tucson Resilient Together plan was adapted to help combat extreme heat and mitigate future climate complications.

Below are examples of Tucson Resilient Together projects that received federal funding:

- **Regional Catastrophic Preparedness Grant Program** funding is being used to create a flexible and scalable plan on how to form resilience hub networks. Resilience hubs are designed to be locations embedded in the community where people feel safe and seek services and resources in times of need - such as a cooling center in the summer.

- **Urban and Community Forestry Program** grant funding is being used for tree planting and maintenance focusing on disadvantaged households and residents with higher heat vulnerability. A multigenerational workforce will be developed to maintain the trees to help increase long-term resilience efforts.

- **Resilient and Efficient Codes Implementation** funding is being used to transform building construction practices across the southwest to achieve highly efficient and climate-resilient buildings and communities, while preserving affordability and regional characteristics.

- Various grant funding will be used to work with the Pima County Health Department, neighboring jurisdictions, local school districts, tribes, and community nonprofits to create a community-wide, comprehensive heat mitigation strategy.

### Table C-1: Tucson Resilient Together Funding Sources (2023-2024)

Table adapted from [City of Tucson’s Resilient Together Climate Action and Adaptation Plan](#).
Funding Provided by State and Local Governments

Adapting to climate change is often achieved through local or regional actions. State and local governments play an important and growing role in the financing and funding of adaptation projects. While many states have authorized grant programs or financing authorities, local funding of resilience and adaptation projects remains important. FEMA’s Local Elected and Appointed Official Guide is a great resource for developing bond issues, special assessments, and taxes for application to resilience programs.

STATE GRANT PROGRAMS

States have implemented a wide variety of grant programs with funding for climate resilience and adaptation. Projects include but are not limited to; traditional infrastructure (e.g., transportation, stormwater, wastewater), green infrastructure, wildlife and biodiversity conservation, flood management, drought, heat waves, and many other outputs. Some programmatic examples include the Virginia Community Flood Preparedness Fund Grant, which was established to help Virginia’s communities mitigate the impacts of flooding; the California Environmental Protection Agency’s EJ Grants, which offer funding opportunities to nonprofit community organizations and Tribal governments to address environmental hazard impacts; and New York’s Climate Smart Communities Program, which provides broad funding to communities for both climate mitigation and climate adaptation.

As there are an ever-increasing number of grant programs, FEMA’s Recovery and Resilience Resource Library is a useful resource for finding new funding opportunities, along with other tools and resources to help craft a strong grant proposal.

STATE-AUTHORIZED FINANCING

Some states have passed legislation empowering local governments to establish districts or authorities whose purpose is to fund resilience projects. For example, the Maryland General Assembly passed SB 457 in May of 2020, which allowed local governments to create Resilience Authorities that can establish a diverse array of financing for a variety of resilience-oriented projects. These authorities can issue bonds, levy fees for services, or rely on government or nonprofit contributions, among other funding streams. In turn, they have a wide range of powers (other than eminent domain) to build, acquire, manage, or operate infrastructure and resilience projects.

California AB 733, enacted in 2017, similarly authorized local governments in the state to create enhanced infrastructure financing districts specifically for climate adaptation projects. Given the broad hazards and impacts associated with climate change, this law provides flexibility for local governments to invest in projects adapting to flooding, drought, and heat waves, as well as the spread of infectious diseases and other public health impacts.

---

Case Study: Climate Protection Fund in Denver, Colorado

On November 3, 2020, the people of the City and County of Denver, Colorado voted in favor of raising the local sales and use tax by 0.25 percent to create the Climate Protection Fund. This fund, which is expected to raise up to $40 million per year, is dedicated to eliminating GHG emissions and air pollution, supporting climate adaptation, and creating new jobs to improve the lives of community members. Its efforts focus on the communities most harmed by climate change: low-income households, communities of color, Indigenous peoples, babies, children, pregnant women, the elderly, people with disabilities, people with access and functional needs, and people with chronic health conditions.

Private and Philanthropic Funding

A variety of private and philanthropic funding is available to SLTT communities in climate mitigation, resilience and adaptation program design and planning. For instance, many large corporations maintain philanthropic programs which may provide monetary support for climate mitigation and resilience building programs. Elected and appointed officials can be helpful in making introductions to business leaders and helping to broker funding for these projects. Planners should consider the value a business may receive from their funding: safer and more resilient communities for their employees, less risk to their operations, or public relations benefits.

Many nonprofits with explicit climate-related risk mitigation and resilience building missions exist across the country. Some focus on specific issues such as wetlands, ocean conservation, sustainable commerce, climate change action, education, or renewable energy. For example, the Wildlife Conservation Society operates a Climate Adaptation Fund that focuses on investment and innovation in adapting wildlife and ecosystems to climate change.

Case Study: Groundwork Jacksonville, Florida

In 2021, Groundwork Jacksonville was awarded $294,000 from the National Fish and Wildlife Foundation, with support from NOAA and AT&T, earmarked for the preliminary (30 percent) design of the Hogans Creek restoration. The goal of the resilience project is to reduce flooding, improve water quality, restore habitat, and provide access to recreation in and around the creek.

The number of nonprofit philanthropic organizations offering funds related to climate-related risk mitigation is rapidly growing. Many of these organizations are members of the National Voluntary Organizations Active in Disaster, making this a good starting point for exploring nonprofits offering climate resilience project funding. The Georgetown Climate Center’s Adaptation Clearinghouse is another great resource where users can search for funding or financing opportunities and filter by region or locality, focal sector, or jurisdictional focus.
Appendix D: Trainings and Additional Resources

Trainings

CLIMATE ADAPTATION AND HAZARD MITIGATION CERTIFICATE PROGRAM

The Emergency Management Institute has developed the “Climate Adaptation and Hazard Mitigation Certificate Program.”\(^{131}\) The program consists of the following courses:

- IS1400 Foundations of Climate Change;
- E1401 Climate Change Fundamentals for Emergency Managers;
- K1402 Climate Change Communication for Emergency Managers;
- E1403 Project Planning with Climate Change in Mind (last course before Capstone);
- E1404 Capstone (must be final course); and
- Three (3) elective courses to be completed at participating colleges and universities.

For a list of elective courses, use key word search such as “climate” in the National Preparedness Course Catalog.\(^{132}\) Potential elective courses include:

- **AWR-347: Climate Adaptation Planning for Emergency Management** trains participants to be able to discuss the impact of weather hazards on critical infrastructure and key resources and explain how climate change projects will affect those impacts. The processes of common weather hazards, climate variability, and climate change will be addressed alongside risk assessment paradigms.

- **AWR-379: Coastal Hazard Awareness** provides training on the basic science of, assessment of, and preparedness for natural hazards and risks that uniquely affect coastal communities. Examples of these hazards are short-term events such as high surf, storm surge, and tsunami inundation, or long-term threats from sea level rise and coastal erosion.

- **MGT-484: Nature-Based Solutions for Mitigation Hazards** provides planners, government officials, and hazard mitigation professionals information on the types, applications, and benefits of nature-based solutions (NBS) as well as the common barriers for their use. Beyond an overview of NBS, the course focuses on the planning and implementation mechanisms that can be leveraged to employ these solutions in practice. This includes planning mechanisms related to land use, hazard mitigation, stormwater management, transportation, open space, and disaster recovery. The course also highlights important planning considerations for utilizing NBS, including planning quality, alignment among plans, and equity.

\(^{131}\) For more information on the Climate Adaptation and Hazard Mitigation Certificate Program, see [https://training.fema.gov/programs/climate-adaptation-certificate/](https://training.fema.gov/programs/climate-adaptation-certificate/).

Additional Resources

ACHIEVING EQUITABLE RECOVERY
The Achieving Equitable Recovery provides local leaders with tools to help identify needs, establish critical partnerships, leverage new opportunities, conduct strategic public engagement, and pursue recovery in an equitable manner. Additionally, case studies, toolkits, and resources are included to help highlight best practices and lessons learned.

BUILDING ALLIANCES FOR EQUITABLE RESILIENCE
Building Alliances for Equitable Resilience includes guidance, perspectives, stories, and resources for equitable resilience.

CLIMATE ESSENTIALS FOR EMERGENCY MANAGERS
Climate Essentials for Emergency Managers offers foundational learning opportunities for the emergency management community and beyond. By sharing communication techniques, climate information, data resources, and guidance for connecting with experts, this resource helps advance the integration of climate change considerations into actionable efforts before, during, and after disasters.

CLIMATE RESILIENCE AND CLIMATE ADAPTATION EXERCISE STARTER KITS
The Emergency Management Toolkit (EM Toolkit) section of the Preparedness Toolkit (PrepToolkit) is intended to provide information on resources that have been developed by FEMA and Federal partners to help the emergency management community at all levels of government to prepare for various threats that face the nation. The Climate Resilience and Climate Adaptation Exercise Starter Kits are specifically designed to provide a set of sample materials and templates that can be customized to create a discussion-based climate exercise to validate plans and policies.

GUIDANCE ON EXTREME TEMPERATURES FOR SLTT LEADERS
Guidance on Extreme Temperatures for State, Local, Tribal, and Territorial Leaders outlines four actions that can be taken by SLTT leaders to help protect people in their respective jurisdictions from extreme temperatures.

LONG-TERM COMMUNITY RESILIENCE EXERCISE RESOURCE GUIDE
FEMA’s Long-Term Community Resilience Exercise Resource Guide offers reliable methodologies, strategies, information and resources for designing and conducting discussion-based exercises focused on climate adaptation and resilience planning. Exercises offer communities a low-risk and cost-effective way to increase preparedness for all threats and hazards, including the potential long-term impacts of climate.

REGIONAL RESILIENCE TOOLKIT
The EPA’s Regional Resilience Toolkit promotes an inclusive, coordinated approach to disaster planning. It is designed to help multiple jurisdictions and levels of government, as well as non-
governmental partners, collaborate on regional-scale actions. It can be used in any region or community — no matter the size, location, capacity, or hazard. The flexibility of the toolkit also allows for the user to jump in at any point in the process, depending on their progress in resilience planning.

RESILIENCE HUBS

Resilience Hubs are community-serving facilities set up to support residents and coordinate resource distribution and service before, during, or after a hazard event. Resilience Hubs are often established in well-managed buildings that have year-round community activities. They are focal points for neighborhoods and provide the resources residents need to enhance their individual capacity while supporting their neighbors. These are run by community members, faith-based groups, and community-based organizations.

RESILIENT NATION PARTNERSHIP NETWORK

The Resilient Nation Partnership Network represents a diverse network of voices united in their commitment to helping communities act and become more resilient toward natural disasters and climate-related events. The mission is to inform, educate, and motivate communities to protect themselves from the loss of life, property, and prosperity as a result of natural hazards.

TRIBAL CLIMATE ADAPTATION GUIDEBOOK

The Tribal Climate Adaption Guidebook provides a framework for climate change adaptation planning in the context of existing tribal priorities, and directly considers the unique issues facing indigenous communities. Specifically, the Guidebook directs readers to the foundation of existing resources and tribal adaptation efforts and identifies opportunities for braiding together traditional knowledges and western science in developing adaptation plans. The framework outline is useful for tribes in different phases of climate adaptation planning efforts and supports learning from the experiences, approaches, and lessons of tribes working to become more resilient to climate change.

U.S. GLOBAL CHANGE RESEARCH PROGRAM (USGCRP) INDICATORS PLATFORM

The USGCRP Indicators Platform is an interagency collaboration that leverages efforts from across multiple federal agencies and highlights key climate information in the form of indicators. The indicators provide information about global and U.S.-based climate and emissions trends. Indicators are based on observed data that can be used to track and communicate climate-related conditions, trends, and impacts. Indicators—which may be physical, ecological, health, or societal—can be used to assess risks and vulnerabilities and help inform resiliency and adaptation planning in a changing climate.
Appendix E: Glossary

- **Adaptation**: Adjustment in natural or human systems to a new or changing environment that takes advantage of beneficial opportunities or moderates negative effects.

- **Cascading Impacts**: Cascading impacts from extreme weather or climate events occur when an extreme hazard generates a sequence of secondary events in natural and human systems that result in physical, natural, social, or economic disruption, whereby the resulting impact is significantly larger than the initial impact.

- **Climate**: Climate is determined by the long-term patterns, over a period of 30 years or more, of temperature and precipitation averages and extremes at a location.

- **Climate Change**: A change in the state of the climate that can be identified by changes in the mean or variability of its properties and that persists for an extended period, typically decades or longer. Climate change may be due to natural internal processes or external forcings such as modulations of the solar cycles, volcanic eruptions, and persistent human-driven changes in the composition of the atmosphere or in land use.

- **Climate Mitigation ("mitigation" also "greenhouse gas [GHG] mitigation")**: Measures to reduce the amount and speed of future climate change by reducing emissions of heat-trapping gases or removing carbon dioxide from the atmosphere.

- **Climate Projection**: The simulated response of the climate system to a scenario of future emission or concentration of GHG and aerosols, generally derived using climate models. Climate projections are distinguished from climate predictions by their dependence on the emission, concentration, radiative forcing scenario used, which is in turn based on assumptions concerning, for example, future socioeconomic and technological developments that may or may not be realized.

- **Climate Resilience**: The capacity to anticipate, prepare for, respond to, and recover from significant multi-hazard threats with minimum damage to social well-being, the economy, and the environment.

- **Environmental Justice**: The fair treatment and meaningful involvement of all people, regardless of race, color, national origin, or income, with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies.

- **Equity**: The consistent and systematic fair, just, and impartial treatment of all individuals, including individuals who belong to underserved communities that have been denied such treatment, such as Black, Latino, and Indigenous and Native American persons, Asian Americans and Pacific Islanders and other persons of color; members of religious minorities; lesbian, gay, bisexual, transgender, and queer (LGBTQ+) persons; persons with disabilities; persons who live in rural areas; and persons otherwise adversely affected by persistent poverty or inequality.

- **Greenhouse Gases (GHG)**: A gas that absorbs heat in the atmosphere near the Earth's surface, preventing it from escaping into space. If the atmospheric concentrations of these gases rise, the average temperature of the lower atmosphere will gradually increase, a phenomenon known as the greenhouse effect. GHG include, for example, carbon dioxide, water vapor, and methane.

- **Hazard Mitigation**: Any sustained action taken to reduce or eliminate the long-term risk to human life and property from hazards.
- **Natural Hazards**: Source of harm or difficulty created by a meteorological, environmental, or geological phenomenon or combination of phenomena.
- **Nature-Based Solutions**: Sustainable planning, design, environmental management, and engineering practices that weave natural features or processes into the built environment to promote adaptation and resilience.
- **Public health**: A science that seeks to protect and improve the health of people and communities. Through policy advice, health education, outreach, and research, public health workers seek to understand and address the root causes of health issues.
- **Resilience**: The ability to prepare for anticipated hazards, adapt to changing conditions, and withstand and recover rapidly from adverse conditions and disruptions.
- **Risk**: Threats to life, health and safety, the environment, economic well-being, and other things of value. Risks are often evaluated in terms of how likely they are to occur (probability) and the damages that would result if they did happen (consequences).
- **Underserved Communities**: Defined in Executive Order 13985 as populations sharing a particular characteristic, as well as geographic communities, that have been systematically denied a full opportunity to participate in aspects of economic, social, and civic life, as exemplified by the list in the preceding definition of “equity.”
- **Vulnerability**: The degree to which physical, biological, and socioeconomic systems are susceptible to and unable to cope with adverse impacts of climate change.
- **Weather**: The state of the atmosphere with respect to wind, temperature, cloudiness, moisture, and pressure. Weather refers to these conditions at a given point in time.
